## DEDICATION

DEAR HAMILTON AND OLGA,

To the many happy days when we have played on your lawn, eaten your bread and salt and drunk your mead—in a changing world to the unchanging symbols of cheer and friendships.

From Horsley, Moosenka, Andy and Perky

## FOREWORD

This monograph represents the studies of a 12 year period in the Pavlovian Laboratory at the Phipps Psychiatric Clinic on the nervous disturbances of dogs. When these psychopathologic reactions were first observed in 1931, it was thought unnecessary to publish an account of the experiments, especially as the early disturbances arose accidentally and the symptoms did not differ essentially from those reported previously by Pavlov. But when the animals were kept for longer and longer periods and more detailed studies accumulated, both as a result of planned experiments and of observations over the life-span of the dogs, new and important relationships between the various pathological symptoms appeared, as well as data on the first subtle and hidden (except to special methods of examination) phenomena of nervous imbalance. An advantage of the prolonged life study of the neurotic animal is evident in Nick, the present veteran of the laboratory, who has now been under observation for 12 years and shown nervous imbalance for a decade. Further justification for the present work is the addition made to Pavlov's studies through the measurements and interrelationships of several autonomic malfunctions, particularly the sexual phenomena. These considerations have led me to organize the material of the laboratory relating to psychopathology.

In the laboratory animal, in contrast to present knowledge concerning the human subject, the spread of the nervous imbalance can be detected before it is overtly expressed, traced from its origin step by step, and followed during its extension to the various physiological systems. Furthermore the prolonged study provides opportunity for investigation of social and personal relationships.

Another delay in the publication of these investigations arose from a change in my point of view. Originally I had felt that more research on the physiology of the conditional reflexes was in order before a successful discussion of the pathology could be completed. Some of this has already been done here, e.g., such as 1) the exponential relationship between amounts of conditional reflex and unconditional stimulus, and 2) the change in heart rate accompanying excitatory and inhibitory conditional reflexes. But though important gaps still exist in the normal physiology, I have become more aware of the impossibility of adequately describing normal and abnormal behavior except in the terms and elements of behavior, notwithstanding the important biochemical, physical, and physiological correlations that should be made at every step.

A pressing need for the study of nervous imbalance is seen in the present and periodically recurring chaotic relations existing among separate nations and peo-

ples. Although the basic principles of conflict are hardly different from those [illegible] have existed for centuries, the means of destruction and organization have been magnified to an alarming extent even in the past 20 years. Moreover, [illegible] balance does not keep pace, either ontogenetically or phylogenetically, with the accumulation of knowledge and the attainments of science. It is a sad but [illegible] commentary that, allowing for individual exceptions, the civilized man has [illegible] advantage over the primitive, nor even the cultured and educated over the ignorant, nor the leader over the follower, in adopting modes of living together [illegible] reasonable harmony and security compatible with our advanced scientific and industrial development. The ignorant and the learned are almost identical when emotionally aroused—whether by avarice, fear, or love. Thus in the face of an emotional crisis, individual or national, we cannot look to any class [illegible] for salvation; though there are many leaders and exhorters, it is only the exceptional man who may provide a solution. Even among our own group of scientific workers, who may consider themselves purified in the cauldron of disciplined thinking, we see now the sad realization of Pavlov's prophecy in 1935—that the same body of scientists gathered together and united in a common effort (at the International Physiological Congress, Moscow, 1935) would in the event of war be seeking as vigorously to destroy one another. War, the parasitic monster feeding on human society, depends not only upon technical economic questions, but upon a specific knowledge of the laws of imbalance, and as no nation can rely either upon immunity or upon always being the victor, it behooves the strong as well as the weak to inquire into these laws.

"In America our most essential problem now that the frontier has gone is to learn to live together" (Alan Gregg). The same applies to the more complex problem of living together internationally. In such a periodically recurring [illegible] world state of affairs any approach to the question of emotional imbalance is important. Though this monograph may have only a remote and at present indirect relation to international problems of upheaval, a study of the emotional [illegible] in the laboratory offers some knowledge, and may open one door for the control of the destructive tendencies that make adjustments difficult, both individually and internationally.

This book begins with the citation of some remarkable examples of the successes of an objective psychopathology. Lest some of the statements appear overzealous, let me interpolate not a recantation but the admission of the fragmentary nature of much of the material, and its need for further amplification and verification in the clinic. In order to study animals over their life span under many and varying circumstances, it is necessary to restrict the number to only a few individuals. Notwithstanding the fact that Nick, for example, has been carefully [illegible] for 12 years (the average life time of a dog and almost one-third the whole productive laboratory career of a research worker) with upwards of 15,000 [illegible]

reflexes separately recorded, he is an example of what happens in only one type of dog; for individual variations are even more striking than the similarities, as will be seen from a comparison of Nick, Peter and Fritz. But in spite of the immensity and complexity of the problem before us, by the piecing together of many controlled observations from the laboratory and from life we may step by step arrive on firm ground in the field of psychopathology.

Though certain facts at the basis of disturbed behavior (such as the development of the anxiety-like state from the original focus over a period of years to involve chronically many physiological systems, the reciprocal relations between conflict and pathological sexual manifestations) have been demonstrated for the first time experimentally in this laboratory and are presented in this monograph—this advance of our knowledge has not yet led me into the temptation of formulating a general system: the awareness of the complexity of the problem and extensiveness of the field has kept me more on a descriptive basis and disposed me to take but a few steps at a time. Though possessing certain advantages in clearness of presentation, conceptual interest, and sometimes the stimulus for further work—the desire to arrive too early at a generalization and systematization often means the end of successful experimentation. To those readers who look for such a systematization, I reply that I am willing to await the time when our knowledge is more complete.

The treatment of my own material is biased to the extent that I have made no attempt to coordinate or to review the work of others. Furthermore I have presented my own work in its chronological development, describing Pavlov's methods and concepts historically rather than critically. Emphasis has been laid on the new facts repeatedly observed, the interrelationship of functions, the early detection and measures of nervous imbalance and the analysis of the underlying factors.

After the historical development of Pavlov's concepts (Ch. I) and a general description of methods (Ch. II), the step by step loss of nervous balance is described beginning with natural emotional shocks (Ch. III) and extending through the various categories of laboratory procedure (Ch. IV). The detailed life history of three dogs subjected to the same difficult routine (Ch. V) precedes the categorical enumeration and interpretation of the symptoms according to physiological systems (Ch. VI) and the results of therapy (Ch. VII). The emphasis on the existence of functional types and the general scheme of detecting the susceptible ones by the careful measurement of their reactions to controlled stresses is given in Ch. VIII, and the concluding chapter presents trial analyses of the states of imbalance described in these studies. Here I have been fortunate in soliciting the interest of three such authoritative psychiatrists as Drs. Ischlondsky, Saul and Leighton to make an evaluation and interpretation of the symptomatology of Nick (in Chaper IX).

This laboratory was started in 1929 on the initiative of Dr. Adolf Meyer. The

first experiments were done in collaboration with Dr. Wolff. He, Dr. Lo[illegible] Dr. Brogden have, in addition to their researches here, also made [illegible] [illegible] contributions.

The colleagues whose efforts in this laboratory have contributed [illegible] or related experiments are, in chronological order: Drs. Harold G. Wolff, [illegible] B. Loucks, Oskar Diethelm, Wendell Muncie, J. S. Light, S. K[illegible] Glen Finch, W. J. Brogden, H. Löwenbach, F. B. Alpern, N. [illegible] Hoffmann, Victor Rosen, M. B. Macht, S. Dworkin, M. Fred [illegible] charts have been made and the MS prepared by Rebecca E. Br[illegible] Ruth Potter I am grateful for the editorial corrections. Dr. John C. W[illegible] generously devoted much time to the reading of the material and given [illegible] able counsel; Dr. Arnold Rich has contributed the experiments w[illegible] secretion and he and Drs. H. M. Thomas, George Thorn, Emmet [illegible] H. S. Liddell have aided me with suggestions. To all these friends I [illegible] grateful.

TABLE OF CONTENTS

## ABBREVIATIONS

C — camera
cs = conditional (conditioned)* stimulus
csi — conditional (conditioned) stimuli
cr = conditional (conditioned) reflex or response
crs — conditional (conditioned) reflexes
UR = unconditional (unconditioned) reflex
URs = unconditional (unconditioned) reflexes
US = unconditional (unconditioned) stimulus
USi = unconditional (unconditioned) stimuli

By using small letters for the conditional response and stimulus and the unconditional reflex and stimulus, the meaning is evident at a glance reference to the logical derivation of the terms—so often confusing to the

Signals (conditional stimuli).
M60 = metronome of 60 beats per minute.
L60 = light of 60 flashes per minute.
T1000 = tone of 1000 cycles per second, etc.
Bu = sound of air bubbling through water.
Be = sound of door bell.

The 24 hour system is used in this monograph, e.g., 1 p.m. written 13:00, 14:00, etc.

The secretory reflexes are expressed in our arbitrary scale divisions where 1 = 0.00167 cc. (parotid) saliva from one gland.

HS = Harry Schmidt, technician in the Pavlovian Laboratory 1944, who worked most with Nick, bringing him down from the dock, putting him in the camera and doing the daily experiments.

RBL = R. B. Loucks, who conducted experiments with Nick, Peter and 1931 to 1935.

AE — Albert Erdman, technician during 1940-42, but never Nick.

WHG = W. H. Gantt, though with Nick in laboratory, less closely with him in the early experiments than HS; with Nick on the

* Conditional and not conditioned is the term used by Pavlov, but since this was first translated English from German and not directly from Russian it is traditionally and incorrectly wr

## I. THE EVIDENCE FOR OBJECTIVE PSYCHOPATHOLOGY; HISTORICAL REVIEW

PSYCHOBIOLOGY and perhaps psychopathology stand on the threshold of a new era. Hardly a science until now, not only can psychobiology at present be recorded in significant objective terms but also some of its elemental data can be formulated as exact mathematical relationships.

As evidence of the recent scientific progress in bringing order and exactness into this field, I shall mention the following:

Pavlov began with the demonstration that the salivary secretion could be used as a qualitative register of "psychical" phenomena (the conditional reflex). This fact alone was an epochal discovery. Later Lyman and Kupalov (*68*) showed that the relation between conditional reflex and conditional stimulus was probably of a logarithmic character, and recently I have adduced evidence that the conditional reflex to a given unconditional stimulus can be expressed in a formula just as the corresponding unconditional reflex or the relationship between two events in the physical world can be.[1] Thus the formula for the unconditional reflex (parotid secretion) is $UR = a + bQ$, i.e., a linear relationship, while for the conditional reflex the formula is exponential, viz., $cr = a + b\,(1 - e^{-cQ})$ where a, b, c are constants for a given dog, UR and cr the unconditional reflex and conditional reflex response in units of secretion, Q the quantity of food by which the conditional signal is habitually followed, and e the base of natural logarithms (fig. 1).

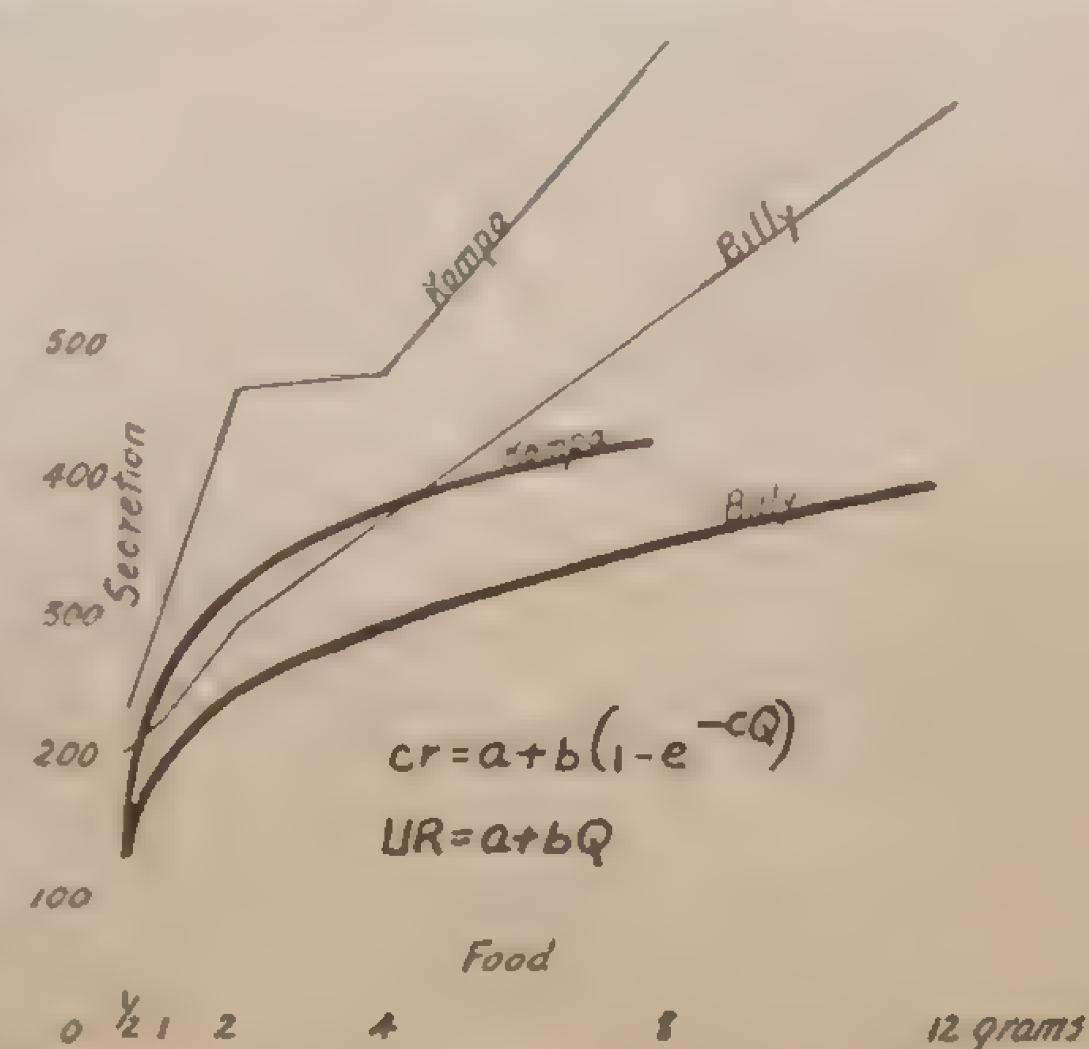

FIG. 1. Relation between stimulus (food) and cr (secretion) and stimulus and UR. Light lines = UR, heavy lines = cr.

Extending the study of the salivary conditional reflex to include allied somatic phenomena, it has been shown in this laboratory that accompanying the nervous

[1] A century ago psychology made a beginning as an exact science with the enunciation of the Weber-Fechner law. However, no great advances occurred along these lines. Here is not the place to discuss the pros and cons of the old controversy as to whether a quantitative or a qualitative description in psychobiology is desirable, or to evaluate the various psychological approaches, as my purpose now is to show briefly what has been accomplished along several lines from a special type of study.

excitation of a bell signaling food (and independent of any effect of the ... or of the muscular movements) there is a definite and *specific* change ... cardiac and respiratory rates, that the cardiac rate is strictly proportional ... amount of food the bell has been accustomed to represent, and furthermore ... if the bell represents inhibition instead of excitation the heart rate is different ... nevertheless specific.

Psychopathology benefits from the exactness of the relations measurable ... above objective methods. Below are examples of pathologic changes in the ... tensity of the conditional reflexes as recorded in the motor, salivary and ... tory, as well as in the cardiac crs.

A dog, Neptune, had been giving perfect differentiation between T256 ... and T384 (–) from 14 February until 22 June. On this day he was placed ... a diet deficient in $B_6$ and pantothenic acid. On the third day after this def... the dog began to show impaired differentiation between the two T... gradually became worse so that there was little or no differentiation after 10 ... When the dog was returned to the adequate diet the differentiation was ... perfect as shown in the reading for 21 October in fig. 2 (experiments with Dr. Wintrobe).

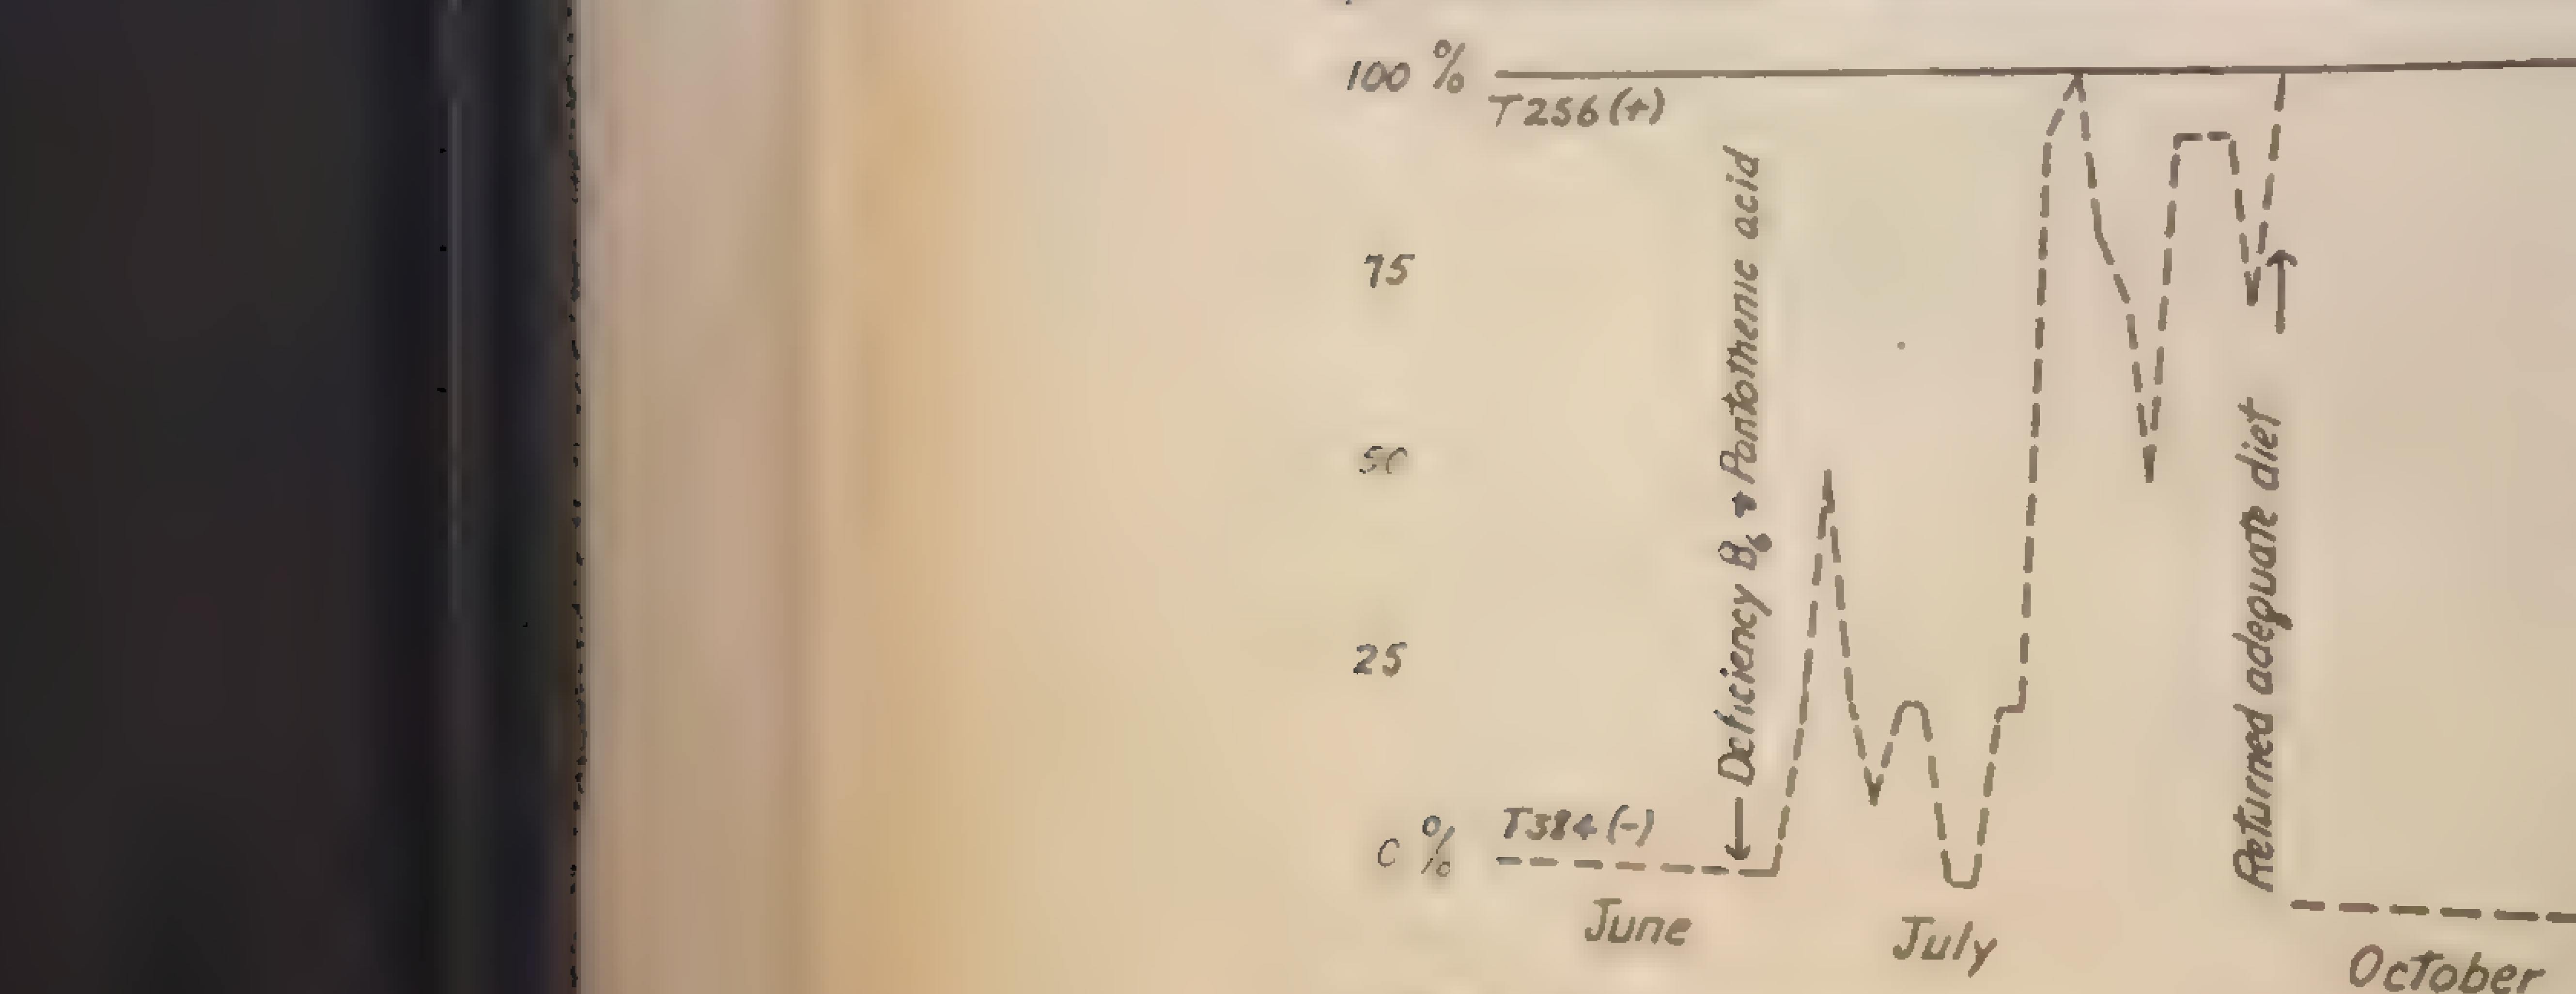

Fig. 2. Impairment differentiation caused by vitamin deficient diet. Ordinates = percent of positive conditioned salivary responses. T256 (solid line) = 100% and T384 (dotted line) = 0 represents perfect differentiation.

In another dog (Nick) ... relationships arose as a re... a psychopathological state, ... all the salivary conditional ... sponses were reduced to z... the chaotic relationships we... expressed in the heart ra... will be shown later (figs. 14, ...

Furthermore in exper... with metrazol used as in... therapy (with Dr. Victor R... both the salivary and the ... conditional responses were ... duced and the inhibitory ones ... creased for a period of six m... in two dogs long after there was not the slightest change in the ordinary be... although this was carefully observed (figs. 3a and 3b).

Thus by a specific quantitative knowledge of the normal laws we are a... able to detect the pathological, earlier than by any other means of ordinary ... servation howsoever carefully made, before the disturbance is reflected in a gen... disorganization, and moreover to say exactly when and how the psychopatholog...

phenomena began. Although this goal has been partly attained in the [illegible] application to the human has yet to be made.

We can point with exaltation to these landmarks of objective progress, [illegible] word of sobering caution is in order. The advance has reached a terminus [illegible] some lines, e.g., in the mathematical statement of the formula for the [illegible] reflex, but the progress has hardly begun in closely allied fields. The [illegible] development makes difficult the correlation and proper use of psycho[illegible] data. Even the use of a formula derived under the strict conditions of the [illegible] tory is generally not applicable to psychobiological phenomena in daily life [illegible] many factors eliminated in the laboratory are active components of the [illegible] tion. Furthermore an equation is unable to express relationships between [illegible] than a few variables.

In spite of the inadequacy of a mathematical statement to express a [illegible] tion of any kind, especially a psychobiological one, the above citations are [illegible] of psychosomatic relationships obeying laws as definite as physiological [illegible] nomena.[2]

Though these examples show where we stand now, it is not without [illegible] review the first hard steps of the journey.

Lightning and flood, famine and pestilence are thought by primitive people to be acts of vengeance from wrathful gods or demons, by analogy to one's [illegible] feelings. The most complex nervous behavior was not subjected to the ordinary methods of science even during centuries of scientific investigation. It was considered as arising spontaneously by analogy to man's subjective feelings. [illegible] science has made inroads upon all of the conceptions regarding inanimate [illegible] it is in keeping with the spirit of the times that we modify this point of view. Now we look upon these events as taking place in a more or less orderly sequence. Thus it is in harmony with the rest of our present day thinking to consider the phenomena of our own psychobiological life as a chain of scientific events; we come to divorce them from our primitive feelings of analogy as we have done the personification of Nature. In the words of Adolf Meyer we are beginning to suspect that "everything concerning the human is accessible to natural science."

Pavlov gave a great impetus to the study of psychopathology when he [illegible] in 1921 a method of producing the "experimental neurosis." Like the discovery of the malarial treatment of general paresis by two Russians in 1888—forty [illegible]

[1] For a more general viewpoint see Gantt (31).

[2] In spite of this there has been a swing away from the former rigid concept of cause and effect [illegible] more plastic one involving the elements of chance. An excellent critical evaluation characterized by a remarkably clear and analytical insight of the role of cause and effect vs. chance in determining human [illegible] was given by Tolstoi in "War and Peace." A more recent article emphasizing the physical [illegible] [illegible] is that of Langmuir (69). See also, Smuts: Holism and Evolution, New York, [illegible]

before its general use—and the early reports of the use of sulphanilamide, these experiments of Pavlov attracted no attention until recently when they have been extended by a good many workers in this country to various animals, from the rat to the primate.

Since the first researches on the experimental animal neuroses originated in Pavlov's laboratory and most of the subsequent work has been based upon his methods, this brief review concerns chiefly the evolution of his investigations and concepts.

No attempt is made in this monograph to list all of the pertinent later work on experimental neuroses[4] nor of the different concepts involved in the whole question of psychosomatic relationships. As I have previously given a critical evaluation of Pavlov (*80*) I shall confine myself in this monograph to the particular historical development of the methods and concepts that underlie the technique (used by Pavlov) which has been made the basis of nearly all the research on the experimental neuroses. To avoid a reference of the method to the underlying concepts would result, it seems to me, in camouflage and confusion. Later in the discussion, different points of view will be given. A clear statement of the Pavlovian concepts does not exclude clinical methods of investigation which make use of, first, additional information derived by probing into the individual's subjective life, through the aid of the extraordinary development distinguishing man from lower animals—the function of speech; nor second, the application of the concept of total integrated action wherever the behavior of the total personality[5] cannot be profitably analyzed into simpler components.

In spite of Pavlov's zealous contentions, it is not my desire to suggest for the Pavlovian technic an exclusive monopoly of objective methodology. A technic is useful which can be universally applied, and varies minimally from observer to observer. Besides being objective the system should deal with *significant* items. The conditional reflex method while neither infallible nor the only objective method, possesses both these characteristics (objectivity and significance) in a high degree. But objectivity is a relative term—any method used for psychobiological phenomena by the subjective human being must carry certain subjective fallacies, as well as errors inherent in the instruments, both human and mechanical. Even though we deal with as imperturbable forces as the passage of light through

[4] An extensive review and bibliography has been written by Masserman (*83*).

[5] From Plato to Adolf Meyer the total organism has received due theoretical recognition: thus "Good physicians apply their treatment to the whole body and attempt to heal the sick part or organ by treating the whole individual" (Plato in Charmides). But progress depends upon not only a balanced perspective and an evaluation of all the significant items and their interactions in the total situation and the organized unit as a whole, but also specific and analytical research directed toward special mechanisms or reactions; witness, e.g., the importance of the discoveries of insulin, of vitamins, and of the brain as the seat of the intellect.

...ence, an improvement of the instruments reveals the bending of the ... by gravitation and led to the theory of relativity. An improvement of ... has also been responsible for detecting nervous breakdown by changes in ... conditional reflexes when others failed to register a change; see in Chapter ... e.g., the superiority of the cardiac conditional reflex over the motor ... index of imbalance.

In the field of literature this principle—dependence of knowledge on the ... instrument—has been recognized recently by Dos Passos (*17*) in a sociological ... where he attempts to describe the changing human instrument of observation ... a series of interpolated chapters entitled "The Camera Eye." Although necessarily highly subjective, the pattern of this unusual novel is a paradigm for both the sociologist and the biographer. Moreover in science there would be much less confusion and fewer irreconcilable theories if greater attention were given to the conditions, methods and instruments (particularly the human) of observation.

An important step leading to the Pavlovian conception of animal neuroses as disturbance of conditional reflex activity was that taken by Descartes[6] 300 years ago when he gave us the idea of reflex. He considered the animal as a machine which reacted to an external stimulus. The connection between the stimulus and the responding organ is made in higher animals by means of a nervous path. The concept of reflex has been used in physiology for more than three centuries, represented in our time by Sherrington's researches on the lower reflexes, and Magnus and de Kleijn's work on such complicated reactions as walking and the maintenance of balance in reference to gravity, showing they are chains of reflexes. An early application of the concept to the cortical functions was made by Sechenov, the father of Russian physiology and Pavlov's forerunner in his book "Reflexes of the Brain" published in 1863.

Pavlov established the idea of the *conditional* or individually acquired reflexes—variable, fluctuating, appearing, disappearing, symbolizing, substituting reactions, whence a delicate equilibrium is maintained in a system surrounded by a changing environment where the system is itself perpetually changing. The cerebral cortex in the higher animals is the chief organ of these plastic and delicate adjustments, keeping the organism in equilibrium with its environment.

The adjustment is made, partly at least, through the mechanism of the conditional reflex. A conditional reflex can be formed between any change in the environment and an already existent activity of the animal. For this it is ... only that the change in the external or the internal milieu of the animal occur once or more in a definite time relation to some previously existing activity, frequently an inborn reflex. A conditional reflex is formed by changing the environ...

[6] The fact that Descartes failed to solve other fundamental biological problems and even made ... errors does not lessen his great contributions to the progress of physiology and science.

ment, e.g., ringing a bell or flashing a light, and following this by an unconditional stimulus, as food or an electric shock. The bell comes to produce a reaction similar to that produced by the food (or the shock); it is now a symbol or signal of feeding, and substitution has occurred. Accompanying the conditional reflex thus formed we say there is present in the nervous system the process of excitation.

In order to maintain and preserve its equilibrium to the fluctuating environment, the cerebral cortex must not only be capable of *synthesis*, but it must differentiate between other changes in the surroundings which have no relation to an inborn activity of biological importance for the animal such as the acquisition of food. The animal must decide between right and wrong, i.e., what corresponds to reality and what does not. Thus false signalization is avoided. This latter process of selection is what Pavlov calls *analysis*.

There undoubtedly exists a reciprocal action between the cortex and other parts of the nervous system and also the whole organism, and all these reciprocities play a part in the psychical life of the human.

The conditional reflexes often become more powerful than the unconditional upon which they are based. Even with the artificial stimuli that we use in dogs we have found that the 60 second secretion to the signal (a bell) for food may be twice as large as the secretion to the actual eating of the food, or the change in heart rate to this signal (cs) as great as the heart rate to the eating of the food (UR). The conditional reflexes under constant conditions are as precise and regular as the unconditional measured by the same method (fig. 4). But this does not mean that they are always the same under constant external circumstances. They may change, as I have shown, with the vacillating internal states of the animal (36). Another of their characteristics is their variability with the individual, the evidence of which will be given in a later chapter.

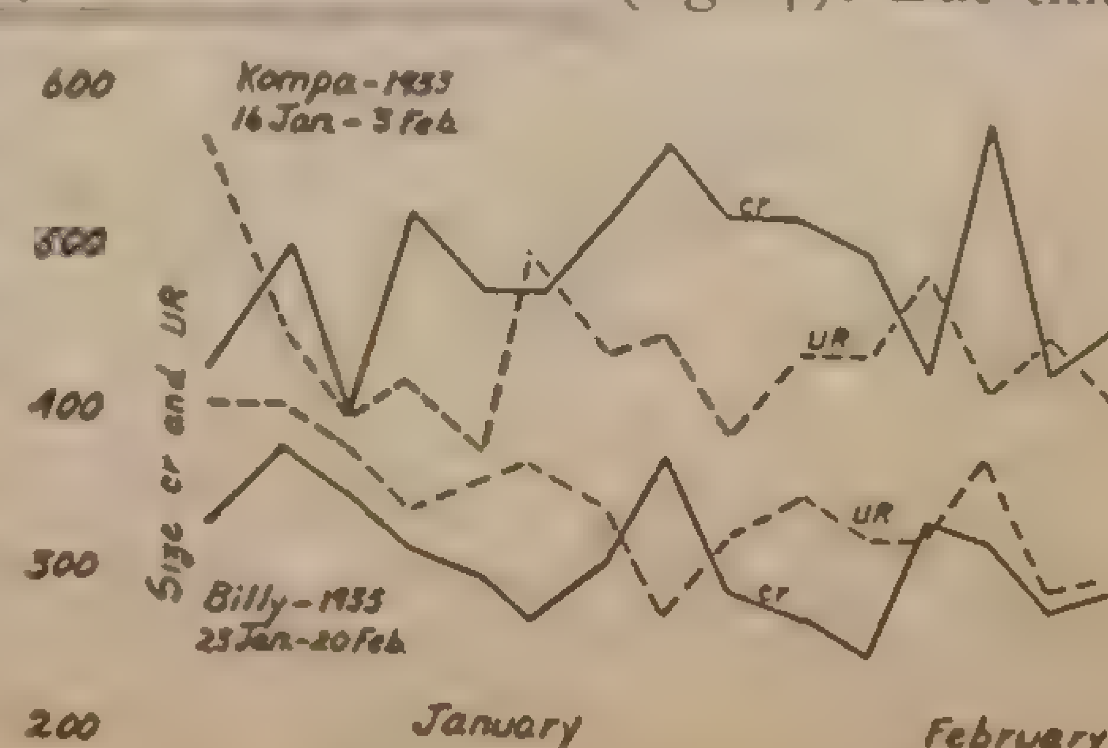

Fig. 4. Comparison of daily variations of salivary cr and UR in two dogs. Solid line = cr; dotted line = UR.

The cortex[1] preserves the equilibrium with a varying environment by means of analysis and synthesis, by choosing from among the mass of stimuli which fall upon it every moment those of biological importance, and by making a connection between any one of these stimuli and some inborn activity or some other acquired activity. The lower, segmental, generic reflexes are limited and fixed—they con-

[1] Recent facts tend toward a less rigid concept of the role of the cortex than was ascribed to it by Pavlov; e.g., the experiments of Zeliony in Pavlov's own laboratory, of Bard, Bromiley (4), Culler, Finch, Shurrager, et al (55).

stitute the *sine qua non* of existence for that species. But the cortex ... creating and destroying connections during the life of the individual, ... bring about and witness the whole panorama of these changes as we ... with the lower reflexes. This choosing between stimuli, reacting to ... failing to react to others is accompanied by two opposed but in many w... cortical "processes"—excitation and inhibition; inhibition as well as ... not a neutral but an active process.

The neurosis was considered by Pavlov a disturbance of the balance ... system and its environment, whose equilibrium* was preserved th... mechanism of the conditional reflex; by virtue of its ability to change, th... in a changing environment or changing organism is preserved. Thus it ... the relatively non-fluctuating unconditional reflex. The UR must sustain ... equilibrium characteristic of the species—it is the foundation upon w... others are built. The differences of experience in each individual are regi... those plastic reactions known as habits, reaction patterns, psychobiological ... and conditional reflexes.

In the dog Pavlov thought that a "neurosis" results from a collision, ... or space, of the processes of excitation and inhibition (see Ch. IV).

The pathologic disturbances may be very slight, lasting only a few minu... they may continue for weeks, months, or years. Examples of both type... described subsequently. The disturbance in equilibri... extend only to the neighboring conditional reflexes, but if it is serious it ... reflected in the external behavior of the animal.

If then the neurosis is a disturbance in balance between a fluctuating org... and a variable environment, and the conditional reflex is one method ... maintaining and measuring that balance, a disturbance in the balance may ... flected in the conditional reflex record. This is a fact as well as a concep... pirically it is known that disturbances of conditional reflex activity in anima... often accompanied by marked observable changes in external behavior ... by certain undeniable emotional evidences, such as deviations in the res... and circulation as will be seen later in the discussion. Conversely, variat... intensity of the conditional reflexes and the balance between excitatory and ... hibitory conditional reflexes may be considered as indicative of an unbala... state of the nervous system. Evidence of this appears in subsequent pages.

Experimental neurosis is the term first applied by Pavlov to the pathol...

* The analogy of physical equilibrium probably is unhappily chosen, as it implies a static rather ... a dynamic relationship.

behavior observed in his animals by this artificial conflict which he set up between "excitation" and "inhibition." The conditions of his animals varied so widely that it would be difficult to identify them with the clinical description bearing the same name. Indeed there is so much to be said for a revision of the clinical terms and the substitution of a more comprehensive and much less rigid one such as that exemplified by Meyer's "ergasiology" than to tie up to an already outworn and shaky structure by the use of identifying terms giving a false sense of security. Notwithstanding the simplicity of Pavlov's phrase "experimental neurosis," I would subscribe to a less rigid concept than that term signifies by the substitution of a more general term, *behavior disorder*, thus avoiding unjustifiable identification with a clinical condition of the same name.[1]

Later Pavlov himself spoke of these conditions as "pathological disturbances resulting from functional interference." His definition of neurosis, however, is sufficiently clear for its use in practice.

As *Neurosis* we understand a chronic deviation of the higher nervous activity, lasting weeks, months, and even years. For us the higher nervous activity is manifested chiefly in the system of conditioned positive and negative reflexes to any stimulus and partially, but to a lesser degree, in the general behavior of our animals (dogs) (*88*, p. 73).

Pavlov's first descriptions (1923) of abnormal behavior as *neurotic* concerned changes in routine of the laboratory procedure.

If I have produced a process of excitation and now limit it with one of inhibition, this is trying on the animal; it begins to whine and bark and attempts to free itself from the stand. The only reason for this is that I have brought about a difficult *balancing* of the processes of excitation and inhibition. Let any one of us consider his own personal life and experiences and he will find many similar examples. If, for example, I am occupied with something—i.e., I am under the influence of a definite process of excitation—and if some one suddenly proposes to me to do another thing, it is unpleasant for me. For it means that I must inhibit the strong excitatory process in which I was engaged, and only after this can I start a new one. "Perverse" children are classical examples belonging here (*88*, p. 333).

But the first experiments from Pavlov's laboratory having to do with pathological changes following conflicting stimuli were much earlier. Those of Yerofeyeva in 1912 revealed the basic facts upon which years later Pavlov built his special concepts.

The conditioned food reflex was elaborated not from an indifferent agent but from a destructive one, evoking an inborn defensive reflex. The skin was irritated by an electric current and at the same time the dog was fed, although at first the feeding had to be forced. A weak current was applied which was later increased to the maximum. The experiment

[1] Korzybski has emphasized in "Science and Sanity" (from which arose Chase's "Tyranny of Words") the harmful effect of such verbal identifications.

applied even with the strongest current, as well as with burning and mechanical destruction of the skin, there could be provoked only the food reaction (the corresponding motor reaction and the salivary secretion) and there was no trace of any interference by the defensive reaction; there were no changes in breathing or heart beat, characteristic of the defensive reaction. It is clear that this result was attained by the transference of the external stimulus to the food center and that simultaneously with this an inhibition of the center for the defensive reactions must occur. This special conditioned reflex persisted for some months and might have remained stable under the given conditions had we not changed them. The electric irritation was systematically transferred at every excitation to another new place on the skin. And when the number of these points became considerable, then in one dog the condition suddenly changed. *Everywhere, beginning with the first location of the stimulus and even with the weakest current there was manifested only the strongest defensive reaction, and not a single trace of the food reaction.*[10]

The next observations of pathological behavior were reported by S[illegible] Krestovnikova in 1921:

A conditioned food reflex was elaborated in a dog to a circle of light projected [illegible] in front of it. Differentiation of the circle from an ellipse of the same size and [illegible] afterwards tried, i.e., the circle was always accompanied by feeding; the ellipse [illegible] Differentiation was thus elaborated. The circle called forth the food reaction, but the [illegible] remained without effect, which is, as we know, a result of the development [illegible] The first ellipse applied was markedly different in shape from the circle (the propor[illegible] its axes was as 2:1). Afterwards as the form of the ellipse was brought closer and [illegible] that of the circle, we obtained more or less quickly an increasingly delicate different[illegible] But when we used an ellipse whose two axes were as 9:8, i.e., an ellipse which w[illegible] circular, all this was changed. We obtained a new delicate differentiation, whi[illegible] remained imperfect, lasted two or three weeks, and afterwards not only disappea[illegible]taneously, but caused the loss of all earlier differentiations, including even the less [illegible] ones. The dog which formerly stood quietly on his bench, now was constantly stru[illegible] howling. It was necessary to elaborate anew all the differentiations and the most [illegible] now demanded much more time than at first. On attempting to obtain the final di[illegible]tion the old story was repeated, i.e., all the differentiation disappeared and the dog [illegible] into a state of excitation.[11]

R.: Contributions to the Physiology of D[illegible] [illegible] Limit of Differentiation by the Visual Analyser of the Dog, [illegible] of the [illegible], vol. III, 1921.

Hypnosis and catalepsy in animals were described to the International Congress of Physiologists at Gröningen as early as 1913, but at that time they were considered only as a state of inhibition and specialized sleep. In his Gröningen address Pavlov said:

> But the matter does not end here. Gradually the effect of the conditioned stimulus, which was more and more delayed, disappears altogether, during the period of its isolated adaptation. It can, however, again be made manifest if the setting in of the unconditioned stimulus is delayed a little more; then you see the action of the conditioned stimulus during the last added seconds. But finally the conditioned stimulus becomes utterly ineffective. At the same time a kind of *cataleptic state* develops in the animal (he appears indifferent to external stimuli and becomes fixed in a certain active pose); or, and this occurs oftener, irresistible sleep follows with complete relaxation of the skeletal muscles. The speed of development and the intensity of the phenomenon upon certain conditions—upon the absolute strength of the conditioned stimulus, upon the interval of time between the beginning of the conditioned stimulus and the unconditioned stimulus, and the number of repetitions of the delayed conditioned reflex. The individuality of the animal has considerable influence. Sleep and the cataleptic state will disappear if the unconditioned stimulus closely follows the conditioned stimulus (three to five seconds). One can hardly fail to see that these phenomena are intimately connected with the nature of hypnotism and natural sleep (*88*, p. 291).

By using the conditional reflex method as a measure for the function of the higher nervous activity in animals Pavlov was able to observe in his laboratory dogs deviations from the normal under certain natural episodes as will be described later.

Pavlov's work on the experimental neuroses expanded rapidly during the last decade of his life (classification of animals into temperaments, the production of conditions which he thought analogous to human psychoses—catalepsy, paranoia, epilepsy, neurasthenia, obsessions).[12]

Pavlov considered that in human neurasthenics and hysterics, the former are like dogs who are incapable of even weak inhibitions, and in the latter inhibition is so pronounced and localized that it takes the form of anesthesias, paralyses and increased suggestibility.

Most of the work from Pavlov's laboratory had to do with either anomalies of the conditional salivary reflexes or the pathologic motor phenomena; little was done on other autonomic functions or the interrelationships of the various systems.

Besides the scores of papers from Pavlov's laboratory in the past few years on the experimental neuroses, recently several American investigators have given serious attention to the subject. First among these were Liddell (*71*) (noteworthy for his work as the American pioneer in this field) and his collaborators. As early as 1924 Liddell turned to the application of the conditional reflex method in the

[12] For a detailed account of these the reader is referred to Pavlov (*89*).

study of the cretin produced by removing the thyroid in sheep. From th[e beginn]ning he and his collaborators (Anderson [2], James [72], Parmenter [...], Liddell et al) have made a systematic investigation of the nervous distur[bance in a] variety of animals—goat, sheep, dog, rabbit, pig. Their routine obser[vations were] made chiefly on the motor conditional reflex in the sheep. Compar[ison of] many species of animals show that the disturbance of behavior was a ge[neral ex]pression of the conflict between excitation and inhibition, but that it took [some]what different form in the different species. Liddell stresses the restraint of [volun]tary activity as a factor in the production of the "neurosis," as well as th[e ...] with the species. Sleep was difficult to obtain, the neurosis being of the exc[itatory] nature because, he suggests, sheep do not normally sleep as do dogs (71).

Anomalies in cardiac rate were noted. Genetic influences have been stu[died by] Stockard, James and Anderson (102).

Extension of the Pavlovian method has been made by Cook (14) Maier [...] and Mowrer (86, 87) to rats; Maier obtained cataleptic states similar t[o those] Pavlov saw in dogs. Dworkin (21, 22), Masserman (83) and Karn (6[...]) [have] described neuroses in cats; Finch (91) and Jacobsen (59) in the chimpa[nzee;] Klüver (65) in monkeys; and Mowrer has worked on social relations in t[...] An extensive review of the American work is to be found in Masserman ([...]

## II. METHODS OF PRODUCING "EXPERIMENTAL NEUROSES"; SUMMARY OF THE SYMPTOMS; METHODS OF MEASUREMENT

DISTURBANCES in behavior have been observed in experimental animals from a variety of causes, some of them accidental, others employed definitely as methods.

Pavlov gives the following summary of the causes of the neurosis:

> Further, with such an experimental animal it is definitely known that this insufficient balance, peculiar to the make-up of the particular animal, finally breaks down under certain fundamental conditions. This happens mainly under three conditions, three circumstances. Either extremely strong stimuli in the nature of conditioned stimuli are used in the place of ones that are only weak or moderately strong and which ordinarily determine the animal's activity; i.e., its excitatory processes are overstrained. Or the animal is required to exert a very strong or a very protracted inhibition; i.e., its inhibitory processes are overstrained. Or, finally, a conflict between both these processes is produced; i.e., conditioned positive and negative stimuli are applied one right after the other. In all these cases with the proper animal there develops a chronic disturbance of the higher nervous activity, *a neurosis*. The excitatory type loses almost completely its ability for any inhibition and generally becomes unusually excited; the inhibitory type, though hungry, refuses even to eat under the influence of the conditioned stimuli and generally becomes exceedingly ill at ease and also passive with the least change of its surrounding environment (*88*, p. 84).

Liddell employed chiefly the third method which he subdivides into difficult differentiation, extinction, and variation of schedule. Maier working with rats has combined pain with difficult differentiation.

In my summary below I have attempted a more detailed analysis, concentrating chiefly on the factors that have appeared in the Pavlovian Laboratory at the Phipps Psychiatric Clinic of Johns Hopkins University. I realize that the detailed classification of the various situations may not rest upon a rational basis, that it may represent associations in the mind of the experimenter rather than in the forces of nature and that subsequent work may reveal an underlying principle which would make such a classification superfluous.

### EXTERNAL FACTORS

a. Natural severe emotional shocks, such as situations involving extreme fear, explosions to simulate military situations, unusual scenes, prolonged and fierce fights, physiological states like parturition, disturbance in the male from the presence (or withdrawal) of a rutting female (see Chapter IV). Most of these states

would ordinarily be recognized by the term "emotional upset." Hen...
ditional reflex method is of great value in giving us a correlated ...
higher nervous activity to compare with what is observed by ordinary ...

SYMPTOMS

The symptoms of the animals studied by me and other workers fall into several categories. First, *general behavior*. Refusal of the animal to perform correctly the problem, or marked deviation from the performance has been most generally observed. Reluctance to enter the experimental environment is seen in both animals and children during difficult differentiations. Second, gross *emotional disturbances*, such as whining, barking, attempting to escape. Defense reactions may replace the food reflex as the basis for excitation. Third, *motor phenomena*, not components of a definite emotion. These varied from great hyperactivity to sleep, catalepsy, convulsions, tics. Fourth, *autonomic responses* (they have been less frequently studied than the motor). Change in heart rate was reported by Liddell and Gantt; frequency of urination by Liddell, Maier, Masserman, Gantt; defecation in pigs by Liddell; change in respiration by Liddell, Kellogg and Gantt; sexual symptoms by Gantt, Parmenter and Anderson. Fifth, changes in the special *relations between positive and negative* conditional reflexes. One or both may be suppressed, or one may predominate at the expense of the other, etc.

The symptoms fall into four general categories in which the appropriate reactions (excitation or inhibition) are replaced by 1) direct active defense responses aimed at escaping from the situation; 2) passive defense, leading to immobility and various motor disturbances (catalepsy, etc.); 3) entirely unrelated and extraneous symptoms, having neither characteristics of the appropriate response nor an active or passive defense value—these symptoms constitute the various neuroses (permanent abnormal changes in the separate physiological systems), as circulatory, sexual, respiratory, alimentary neuroses. 4) Changes observable only by special measurements of occult autonomic functions.

Upon the latter we depend for the most delicate measurements of the imbalance in the animal. As one may deduce from the theoretical considerations of Chapter I, a disturbance in the organism can be reflected in the conditional reflexes of that system where the disturbance had its origin, e.g., with the food reflexes if the original focus was food. These conditional reflexes may be diminished or reduced to zero, but lacking such gross changes, we have more delicate measurements, viz., in the relationships of the different conditional reflexes. Thus the inhibitory conditional reflexes may suffer and not the excitatory, or vice versa; the strong and not the weak, or the ratios may be altered as described by Pavlov (paradoxical phases). Also the accompanying respiratory and cardiac conditional reflex records may show anomalies and chaotic relations instead of the previous regularity. As a rule the secretory and motor *unconditional* reflexes are not affected, but measurements of another important unconditional reflex prove to be a delicate barometer of the disturbance, viz., the sexual reflexes. Their susceptibility to imbalance in

other systems (e.g., food and defense) is in strong contrast to the ... munity regarding susceptibility of the other unconditional reflexes.

Change in 24 hour running activity in the cages has also furnished ... of chronic nervous imbalance. Besides the evidence in the sudden ... the usual degree of activity is the lack of correlation between the ... pathological animals with the normal.

In any measurement that we make—whether general behavior, ... tory, respiratory, cardiac, metabolic—it is imperative to recognize ... *measure represents the whole picture.* We are, so to speak, fishing ... of life, and bring up only that for which we have the appropriate ...

The establishment of the laws of conditional reflexes in the ... referred to in Chapter I, furnish the basis for detecting the patholo... ing the variation from the normal. The dog is thus separated in the sou... camera from all adventitious stimuli.

After the above habituation of the animal to the environment ... so that he stands quietly, the routine experimentation is begun by ... visual or tactile stimuli at intervals of 3-5 minutes. Each such ... duration of 10 seconds, after which a measured amount of food is ...

mechanically in front of the dog. The animal gets 10–12 such stimuli and feedings daily, spending 30 to 90 minutes in the closed camera.

After a *stable* positive conditional reflex, which requires from 1-6 months depending upon the animal, has been established, the development of inhibition (differentiation) is started. A similar though easily distinguished stimulus is chosen as a negative one to be differentiated from the former positive cs. Thus if M20 were the positive signal, M100 (metronome with a frequency of 100 per minute) might be the negative stimulus. Such differentiation may require another 6 months' period for stabilization. The measure of the inhibition is the amount of salivary secretion during the action of the negative stimulus, usually taken for 30 seconds. After one positive conditional reflex has been formed subsequent ones can be established more quickly. The measurements made are shown in Table 1.

TABLE 1

DOG: BILLY — 21 OCTOBER, 1931

| Order of Stimuli Interval | Conditional Stimulus | | | | Orienting Reflex | | Conditional Reflex | | | | Reinforcement (Unconditioned Stimulus) | Size Unconditional Reflex (in seconds) | General Behavior Remarks |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Time | Conditional Signal | Number for Repetitions | Duration in Seconds Isolated / Total | Latent period (seconds) Strength | Duration (seconds) | Latent Period (seconds) Secretory | Motor | Size of Secretion | Motor Reflex | | | |
| 1 | [illegible] | [illegible] | 212 | 15 [illegible] | +1–15 | | >1 | — | 175 | — | 3 gms | [illegible] | Dog [illegible] the [illegible] experiment |
| [illegible] | [illegible] | [illegible] | 213 | 15 [illegible] | +1 15 | | 2 | — | 222 | — | 3 | 274 | |
| [illegible] | [illegible] | [illegible] | 214 | 15 [illegible] | +1 5 | | 4 | 5 | 225 | + | 3 | 175 | |
| [illegible] | [illegible] | [illegible] | 215 | 15 [illegible] | ++5–15 | | 3 | [illegible] | 250 | — | 3 | [illegible] | |

From the above it is seen that we have a measure for the intensity of both the cr and UR, the latent period of the cr (time after the beginning of the conditional stimulus that the secretion starts), and the motor component (turning of the dog toward the source of food during the action of the conditional stimulus).

In the development of the defense conditional reflexes (crs) a secretory measure may be made by injecting 0.25 per cent hydrochloric acid into the mouth 10 seconds after the beginning of the conditional stimulus (cs) instead of giving food.

Simpler than the above secretory methods is the establishment of the motor defense reflexes to a faradic shock to the paw. The cs is given for 1 to 3 seconds at intervals of 1-5 minutes, the dog being in a soundproof camera. The duration of the cs is always constant, i.e., either 1, 3 or 5 seconds, though the interval between the successive conditional stimuli varies from 1 to 5 minutes (in order to avoid the establishing of a time reflex). Any movement of the animal during the cs suggestive of or similar to the movement which the dog gives to shock is recorded as a motor cr. Its latent period is measured from the beginning of the action of the cs.

Although the motor defense crs are not routinely measured quantitatively[1] as

[1] Liddell uses the Fick accumulator to obtain a quantitative measure of the movements.

are the salivary than are easier to record, and it is not necessary to maintain a constant state of hunger in the animal as it is when one is using the food; with the latter, this is essential (to produce tension as the food [illegible] the dog is ordinarily starved for 22 hours before the experiment, receiving his daily ration as soon as he is returned to the paddock). Furthermore in the [illegible] we have developed here we probably possess a much more delicate [illegible] excitation than is possible with any method for muscle movement [illegible] tried one for action currents. The cardiac CR (Gantt [46]) and Gantt [illegible] which I have been using for several years as a measure [illegible] more responsive than any other CR record.

It is important to remember that the CR whether it is secretory, motor, or respiratory, is measured during the action of the CS, and the unconditional [illegible] (UR) is measured after the dog receives the unconditional stimulus (US): the food, the acid, or the shock.

For a fuller description of methods see the excellent book of Hilgard and Marquis ([illegible]), Postkopaev ([illegible]), Liddell (72), and Gantt ([illegible], [illegible]).

## III. PRODUCTION OF DISTURBANCES IN BEHAVIOR BY NATURAL EMOTIONAL SHOCKS, TRAUMATIC AND EXPERIMENTAL WAR NEUROSES

MANY EVENTS occur during even the controlled laboratory life of the dogs, especially if they are not kept in separate paddocks, that have a profound effect on the behavior of the individual. Ordinarily this might pass unnoticed but where a detailed careful study is made slight deviations from normal appear in the conditional reflex interrelations, calling attention to the disturbance as well as measuring it more delicately than any ordinary observation can. By following the dogs over a large part of the life span and the making of daily conditional reflex measurements, I have been able to detect frequent abnormalities of behavior and to find the causes in some experience of violence.

Doubtless innumerable instances of nervous behavior have been seen in domestic animals from time to time, but owing to lack of careful observations of the symptoms, of the isolation of causes, and more particularly of the use of a satisfactory and delicate measure such as we have in the crs, they are not available in the literature for study and comparisons. Several verified examples will be given later in this chapter.

Physiological conditions that cause a change in the crs are the postpartum state in the female and sexual excitation in the male. Pregnancy is without effect up to within a few hours of labor. In many females who had had good differentiation up until or shortly before parturition, for several days postpartum there was a lack of differentiation between positive and negative crs as well as some panting and restlessness while the dog was in the experimental camera (Table 2).

TABLE 2

KOMPA

| | | |
|---|---|---|
| 15 Dec. 19[illegible] | M6[illegible](+)=1[illegible] | M144(−)=[illegible] |
| 27 Dec. 19[illegible] | Puppies born | |
| 2 Jan. 1931 | M6[illegible](+)=1[illegible] | M144(−)=16[illegible] |
| 5 Jan. 1931 | M6[illegible](+)=[illegible] | M144(−)=150 |

After pregnancy a loss of differentiation is seen.

A similar disturbance was observed in a quiet stable animal, Zee. Although there was no change in her observable motor reactions to the positive tone 256 and the negative tone 512, a comparison of the cardio-respiratory crs shows a chaotic relationship shortly after labor. This dog had puppies on the night of 16 April. When she was tested on the morning of 17 April there was increased heart rate as

TABLE [illegible]

[illegible] Heads Raised [illegible]

| | [illegible] Mar [illegible] | | [illegible] Apr [illegible] | | [illegible] | |
|---|---|---|---|---|---|---|
| | Control | No readings | Postpartum [illegible] | No readings | [illegible] | [illegible] |
| Heart rate [illegible] | [illegible] | [illegible] | 142 | [illegible] | | |
| Heart rate [illegible] | [illegible] | [illegible] | 142 | [illegible] | | |
| Heart rate [illegible] | [illegible] | [illegible] | [illegible] | [illegible] | [illegible] | |
| Heart rate [illegible] | [illegible] | [illegible] | [illegible] | [illegible] | [illegible] | |
| Heart rate [illegible] | [illegible] | [illegible] | [illegible] | [illegible] | [illegible] | [illegible] |
| Heart rate [illegible] | [illegible] | [illegible] | 120 | [illegible] | [illegible] | [illegible] |
| Heart rate during UR | [illegible] | [illegible] | 117 | [illegible] | [illegible] | [illegible] |
| | Quiet | | Restless | | Quiet | |

well as a failure of the normal differentiation between the control hea[illegible] the heart rate to the positive cs, i.e., the heart rates on the 17 April d[illegible] the normal relationship that they did previously, as can be seen in Table [illegible]

On the 10 March (during pregnancy) the increase in heart rate with

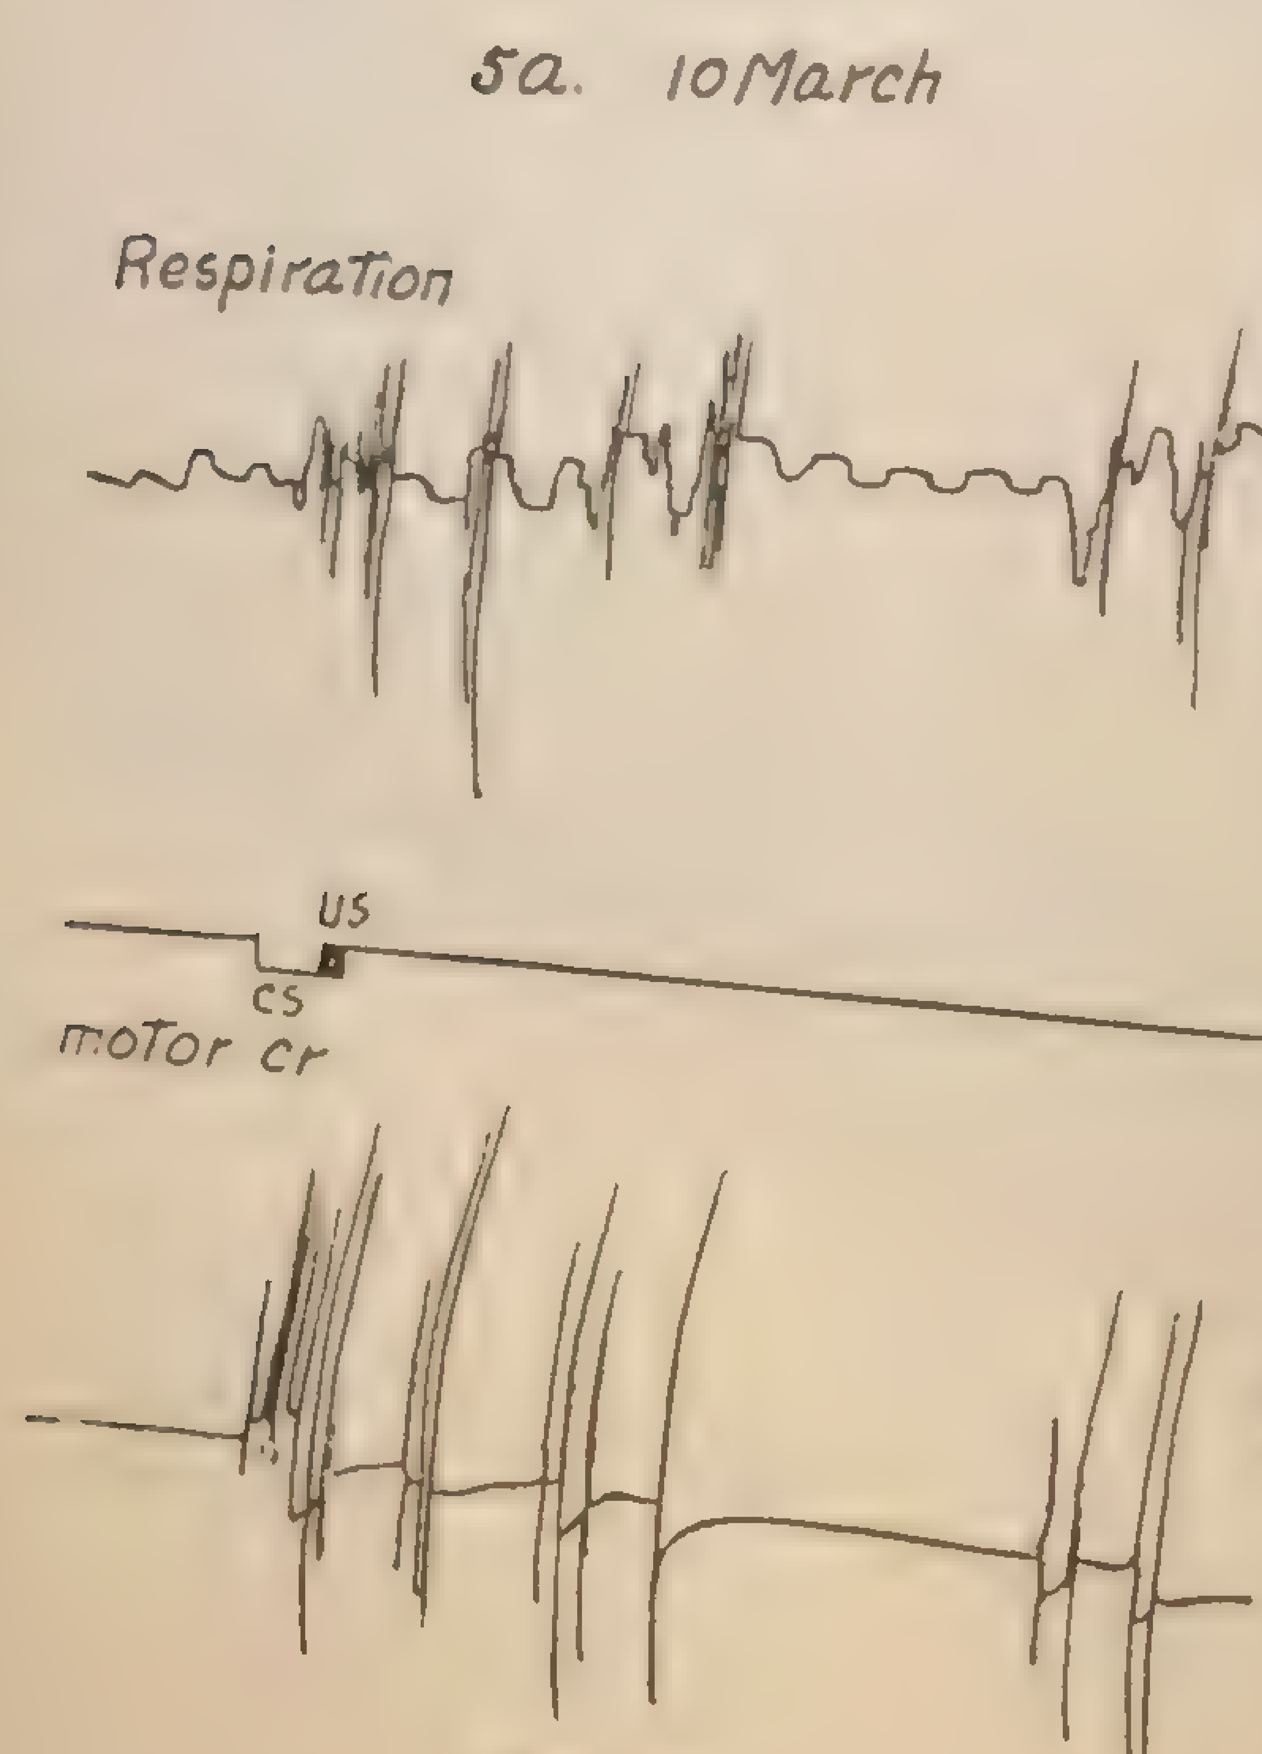

Fig. 5a.

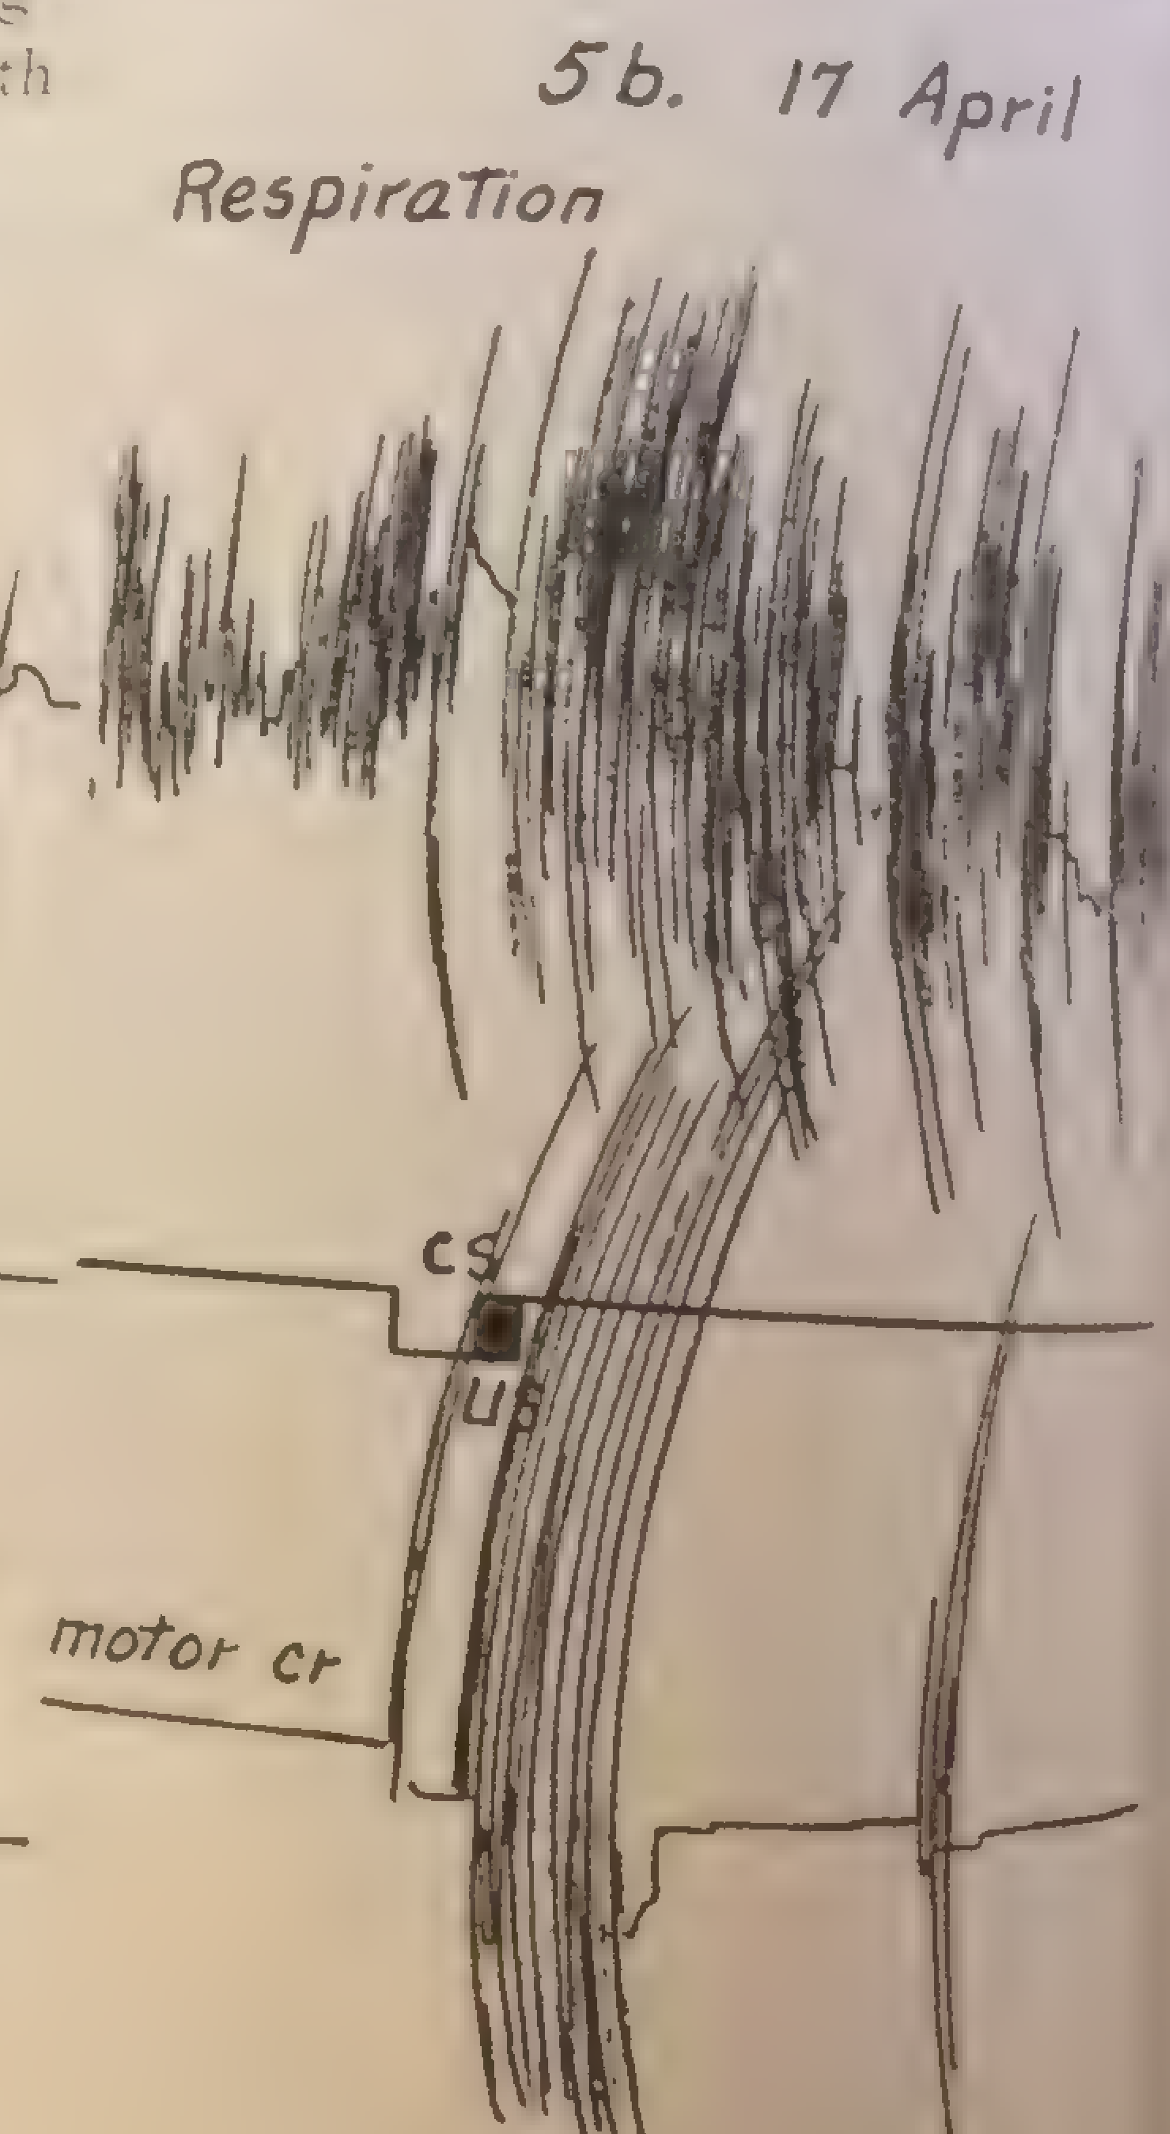

Fig. 5b.

and positive cr was from [illegible] to 100 ([illegible]%), with the negative cr [illegible] to [illegible] ([illegible]%), while postpartum on the 17 April, the increase of the heart rate was with the positive cr only [illegible] to [illegible] ([illegible]%) and with the negative cr paradoxically more than it was with the positive cr, viz., [illegible] to [illegible] ([illegible]%). One week after birth the postpartum cr heart rates were approximately the same as during pregnancy.[1]

There is a corresponding change in the respiratory rates on the three days as is seen in the records below; the rate on 10 March is approximately [illegible] per minute, on 17 April 150 per minute, and on 24 April the respiration was again normal with short intermittent periods of panting (figs. 5a, b, c).

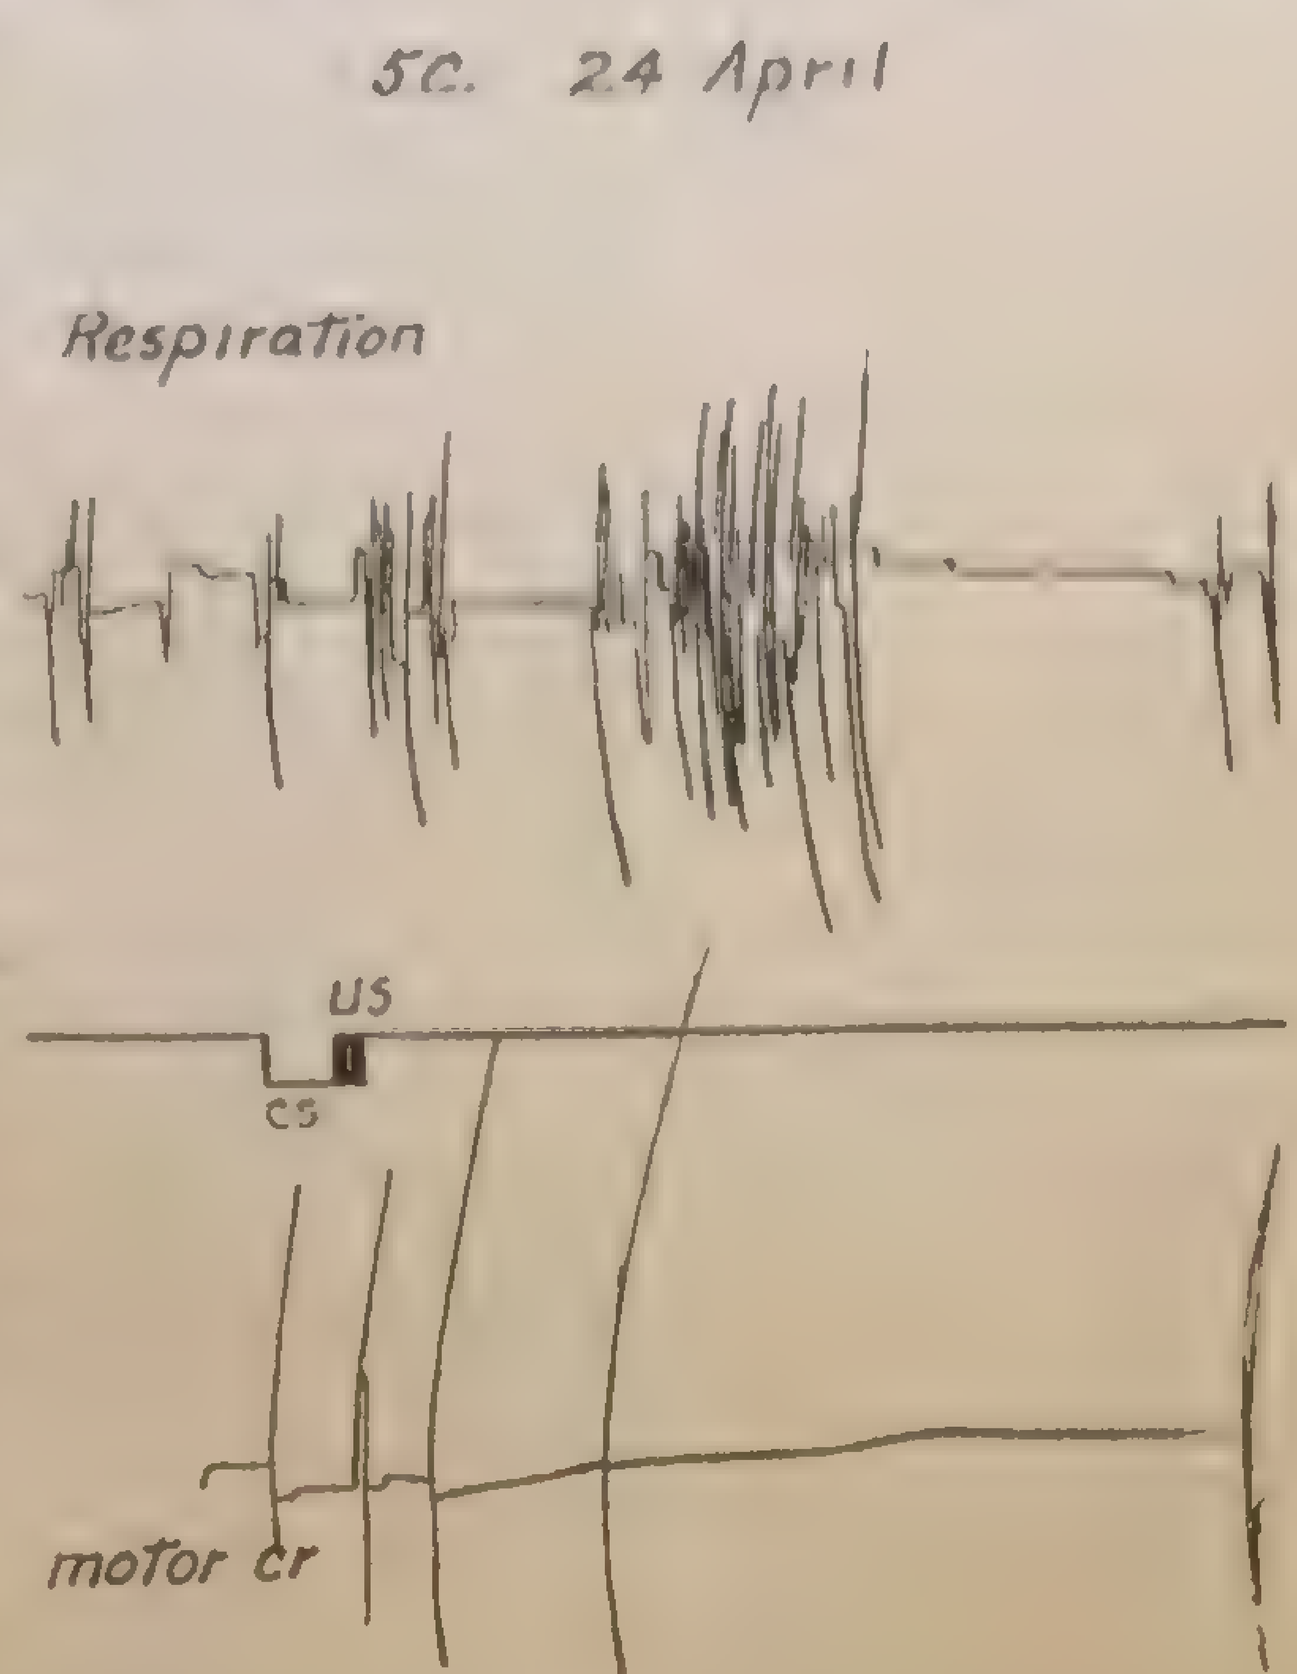

FIG. 5c.

FIGS. 5a, 5b, 5c. Respiratory response and motor reflexes in dog Zee a) in late pregnancy, b) 10 hours postpartum, and c) one week postpartum. Note the greatly increased respiration rate and the more frequent and intense movements of the leg in Fig. 5b.

The stimulation of being in the same room or near a female in estrus has a powerful effect upon male dogs. Not only does it affect their behavior, making them more restless and hyperactive, but it has a marked disturbing effect upon the crs. Thus a dog Bamech in the same room with a female in estrus (in which there were also many other dogs) would not eat that day in the experimental camera. At this time he likewise showed marked restlessness—turning around on the stand, jumping up, backing off. Furthermore the secretory crs became paradoxical, i.e., the weaker ones were stronger than the formerly strong ones. (Experiments of Dr. Dworkin. Ch. IV, see Table 5.)

As pointed out in the discussion of Nick, the sexual excitation in a female dog has a less powerful effect as an inhibitor of other functions than it does in the male. Thus a bitch continues to accept food in the presence of a male during estrus and

[1] The equality of the positive and negative cr heart rates was due to the fact that Zee did not differentiate on any of the above days between the excitatory and the inhibitory csi, i.e., she lifted her foot to both positive and negative csi.

even during coition, although a male is capricious about taking food [illegible] during estrus. H[illegible] ence of the female in estrus, refusing it completely after [illegible] is no effect upon the secretory crs in the male shortly analyse what might [illegible] these observations it has not been possible to frustration, etc. factors such as the presence of other male dogs, frustration, etc.

Besides physiological states and the occurrences that upset the [illegible] *infra*), in a series of dogs fearful influences were introduced, simulating [illegible] and fright of war and bombing. A striking example of the accidental [illegible] normal behavior occurred in the Pavlovian Laboratory at the Johns [illegible] Medical School in 1931. About 15 dogs were accustomed to being [illegible] in two paddocks on the sixth floor. They were always brought down [illegible] leash to the experimental camera on the first floor. On Sunday, 19 A[illegible] they were discovered roaming over the 3rd, 4th, 5th floors in [illegible] to the paddocks having been left open apparently on Saturday night. O[illegible] the pandemonium—barking, fighting—the night watchman was met at [illegible] of the steps by growling animals which he said were like a pack of [illegible] tempting to attack him. A panic resulted in which he clubbed the dogs [illegible] getting them back into their places around noon. His attitude was described [illegible] he said there was so much difficulty that he would have shot them if he had a pistol. The next morning the animals had more or less severe injuries [illegible] sprained legs, gashes on the face, etc., from the beating and the scuffle [illegible] themselves.

Following this weekend debacle, there was a marked change in the [illegible] behavior as well as in the crs of the animals. Furthermore the alter[illegible] the behavior and crs varied with the constitutional temperament of the [illegible] ing from one or two days in the milder cases to a week in the severe, [illegible] time it became nearly normal except in one of the dogs, "Blue."

The following three dogs showed contrasting and interesting changes:

"Kompa" ordinarily was a lively animal of the excitatory type, [illegible] jumping around, playing, sniffing for food; never quiet a moment except [illegible] in the experimental chamber. On 20 April the day after the escape, she was [illegible] what subdued in her activity, but more active than any of the other animals.

Formerly there was a good differentiation to the metronome as shown [illegible] protocol for 17 April, i.e., there was no secretion ordinarily to M140 (negative, never followed by feeding), though a secretion of 150 to M60 [illegible] feeding). After the panic, on 20 April the secretion at 14:33 o'clock [illegible] 60 seconds was 75 instead of 0, and at 15:02 the secretion was 50 instead [illegible] The secretion to the positive crs was unchanged. On 22 April the secretion [illegible] 15:00 to M140 was 25 for 60 seconds, and at 15:22, 13 mm.; on 24 April [illegible] mm. at 15:07, and 63 at 15:27. Comparing these readings with [illegible]

protocols on 15 April, before the accident, we find that the reaction to M[illegible] was only 5 mm. secretion, i.e., nearly perfect inhibition.

This dog, of the excitatory temperament, under the stress of the disturbing experience, suffered only a slight decrease of her positive (excitatory) reflexes, but the inhibitory or negative ones were transformed into excitatory ones, shown both by the salivary secretion and the substitution of restlessness for the usual sleep with the inhibitory metronome. Previously it was seen with Kompa, that the inhibitory reflexes were much more unstable, i.e., they changed their character completely or fluctuated more from day to day than the excitatory; these latter were strong and persistent, not changing after several months' interval.

The next dog, "Blue," usually a lively, playful animal, varied greatly however in his mood, being easily offended, often seclusive and fearful and always disobedient. Judged by the speed of formation of crs, his intelligence was about the same as that of Kompa but his retention was not so good.

After the accident of 19 April he suffered a serious change. He could be brought only with difficulty into the experimental room, although generally he ran there with avidity. Instead of scampering about and playing before being put into the camera as he ordinarily did, he crouched in the corner with tail tucked, back arched, and would not come out when called or offered food, did not jump upon his master as usual; sat in the corner for an hour at the time, resisted being brought out, hung his head and could not be induced to look up at the experimenter. When we moved him out of the corner in an attempt to play with him, he slunk back as far out of sight as possible. Although he generally went eagerly for a walk, now he resisted; he did not tug on his leash as usual but had to be coaxed. He ran away from the other dogs with tail tucked. This behavior was most marked on 20 April, returning gradually to normal. On 27 April he was playful again, jumping on the chairs and on the experimenter, but in a more subdued way than formerly.

When put into the experimental camera he was very quiet instead of lively and playful. For the week following there was no barking or playing whatever. The crs (which were present on the 16 and 17 April, though rather irregular then) showed marked alterations: to M20, the stronger of the csi, they entirely disappeared the day after the episode; and to the weaker cs (Bu), they were greatly diminished (both of these were positive csi). Furthermore there was a reversal in the normal reaction to these stimuli, in that he usually gave a larger secretion to M20 than to Bu, as the former was the older, having been repeated 104 times while Bu had been used only 14 times (date of 20 April). This phenomenon will be met later as the "paradoxical phase" of disturbance in the normal relations of the crs. On the 24 and 25 April the crs returned, but they were smaller than they were before the 19 April, irregular, and not even present every time.

In the protocol for the 2[illegible] April, we see that they had all returned, and moreover approximately of normal intensity for this animal.

The third dog, "Billy," was a bull terrier, the cleverest of any of ... elaborating the cr after two trials and becoming regular in his reactions after eight repetitions of the stimulus with food. He was also well balanced, ... ing differentiations easily in contrast to Kompa and Blue.

Obedient, purposeful in his movements, orderly, and accurately re... situations, he was altogether a well disciplined animal—not playing ... vited to do so nor jumping on his master except when called, in cont... who tore up paper, jumped around on the chairs, tables, and food box, ... the loops; on the contrary, Billy would sit quietly in the experimental ... hours. But on appropriate occasions he was playful and vivacious, running ... into the camera, tugging and pulling when taken for a walk. Extrem... with the other animals, he often fought severe battles with them, in spi... fact that he had received serious wounds from these scuffles himself, having ... a perforation through the cheek, a badly bruised leg, lacerated ear, etc. H... ered these vicissitudes well, however, showing little change in his beh... his reactions to the conditional stimuli. There is justification, in contr... and Kompa, in saying that he has a strong, well-balanced nervous system.

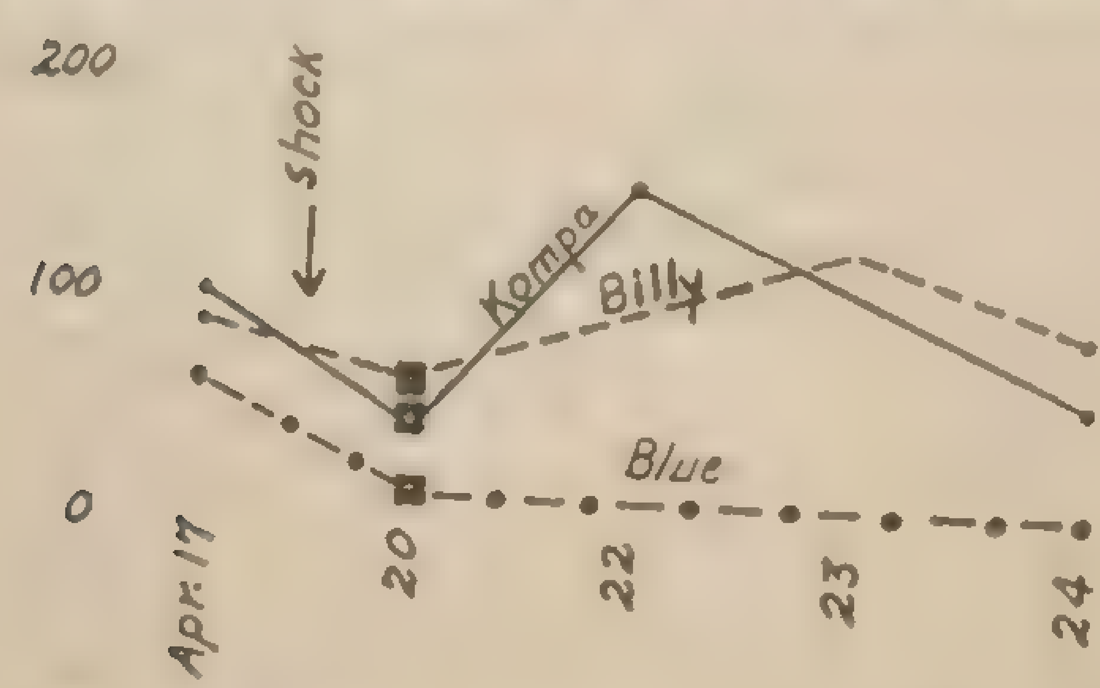

Fig. 6a. Effect of natural emotional shock (escape from paddock) on cr in 3 types dogs—excitatory labile (Kompa), stable (Billy) and inhibitory labile (Blue).

After the debacle of 19 A... dog's behavior changed only ... compared to the other dogs. H... somewhat less active and playf... normally; he did not play ... brought down, nor tug a... on the leash when taken for ... The crs were altered very ... slightly decreased and less wel... ferentiated, but only for the on... 20 April (fig. 6a).

Summarizing the effect of ... on these three animals of different temperaments:

First, the behavior of all three was altered somewhat. This was shown i... the general behavior and the crs.

Kompa, a strong excitatory type having a capable nervous system for exci... stimuli, in that the positive reflexes are nearly always active and present, ... a slight change in her behavior and for four days a breakdown in her reac... only to the inhibitory or negative stimulus.

Blue, who was frequently irregular in his reactions and almost neuro... his behavior at times, sometimes very excitable, became excessively subdued...

depressed for the whole week, almost comparable to a deep depression (while Kompa was always excitable). Experimentally he had a complete loss of crs, reversal of effect of the strong and weak stimuli from the first day (Pavlov's paradoxical phase), and irregularity for the entire week, with gradual recovery. His general behavior also showed progressively less depressive reactions, but remained abnormal throughout the week.

Billy, with a strong, well-balanced nervous system, showed very little change in his behavior and even less in the crs, returning to normal in two days.

Confirmatory of what occurred in these three dogs in April 1931, there was later another similar disturbance. In attempting to produce an artificial neurosis (experiments with Oskar Diethelm) we subjected Kompa and Blue to attacks by fierce bull dogs. With Kompa the attacking dog (Lady, referred to subsequently) was muzzled as otherwise she would have speedily killed Kompa. With Blue we allowed the dog (Billy) to attack unmuzzled, but we muzzled Blue, and removed the attacking dog by strangling whenever there was danger, although the long hair of Blue was a partial protection. Kompa and Blue were tied in a corner so that they would not escape (Table 4).

TABLE 4

SUMMARY OF EFFECTS OF FIGHTING ON LABILE AND STABLE DOGS

| | Before Fight | | | After Fight | | |
|---|---|---|---|---|---|---|
| | +cr | −cr | UR | +cr | −cr | UR |
| *Labile Dogs* | | | | | | |
| Blue 1932 | 40 | | 550 | 0 | | 68[illegible] |
| Kompa 1931 | 165 | 20 | 415 | 165 | 75 | 55[illegible] |
| Kompa 1931 | 115 | 0 | 540 | 120 | 50 | 61[illegible] |
| Kompa 15 Mar. 1932 | 150 | 0 | 545 | 0 | 0 | 39[illegible] |
| *Stable Dogs* | | | | | | |
| Lady 1931 | 260 | | 160 | 240 | | 16[illegible] |
| Billy 1932 (a) | 400 | | 700 | 450 | | 61[illegible] |
| Billy 1932 (b) | 250 | | 250 | 200 | | 18[illegible] |
| Billy 15 Mar. (c) | 50 | | 520 | 65 | | 525 |

(a), (b), (c) = crs of different intensities.

Both Blue and Kompa attempted to escape, but finding that impossible they became prostrate, snapping back ineffectually. There was marked dyspnea. The panic was intensified by kicking Blue and Kompa, though not painfully, during the fight.

The results were parallel to what was seen before. With Kompa there was in the two experiments very little change immediately after the struggle in the positive crs but a slight breakdown of inhibition. The positive crs were remarkably stable, the Bell (Be) giving 165 before the assault and after it at 16:38 a secretion of 164 and again at 16:55 a secretion of 165. The second time the fight was staged

the bell gave 113 at 14:24 before the attack, and a secretion of 130 at 14 ... minutes after the attack, a secretion of 126 at 14:53 sixteen minut... second attack. This variation is less than what we usually get in our m... on normal days.

The intravenous injection of 1 cc. of adrenalin in Kompa apparently ... the same type of disturbance in the crs as the fight, viz., little effect ... tive conditional reflexes but conversion of the negative into excitatory ... ments of Oskar Diethelm, 1931). This was not due to an effect up... tory glands because the URs were not increased. (See Table 22).

With Blue the story was different. The fight took place on 4 Janu... after the routine tests had been made. At 16:30 Billy and Blue were bro... together. Billy, a fierce Pit Bull Terrier was allowed to fight Blue wh... zled. Blue lay on the floor where he was tied, bared his teeth and tried ... Though Billy attacked Blue vigorously he did not injure him on accou... long hair. Blue was kicked, though not painfully, during the fight by ... perimenter. When Blue was tested even two days later, it was seen th... 5″ crs were absent except the second one. This is an occurrence that had ... pened since Blue's crs had become well established several months ago. ... 7 January the 60″ measurements of the stimuli Bu and M20 were pr... equal, closer together than they had been since the first day of regular diff... tion; their normal ratio is 7:10. This is, as we shall see later, the phase of ... zation—a pathologic stage less severe than the paradoxical phase noted ea... Blue.

In the attacking dogs Billy (the stable animal of our first series) an... there was no change in the reflexes recorded on the day following. Table ... trates these changes in the various dogs.

Another instance of a natural conflict between two of the above mentione... Kompa and Billy, occurred on 18 March, 1932. These animals were eng... a prolonged battle, probably lasting for 12 or more hours. They were se... severe fight at 7:30, and again at 14:30. The description given of the two ... at that time was:

"Billy was holding on to Kompa's leg who was trying to pull away. Both ... were severely wounded, too weak to stand up, but lying down fighting ... there were gashes on ears and cheeks, the face was swollen when brought ... experimental room at 17:00; he did not play, nor run about nor jump up ... as he usually does but was much subdued though not nearly so much as K... for he ran into the camera, jumped on the table by himself and came whe... When coaxed he put his forefeet out toward the experimenter. But he w... lively, walking slowly and jumping only feebly for crackers. *Kompa:* there ... eight deep tooth gashes on her legs extending into the second layer of the ...

The wounds on Kompa and Billy seemed of equal severity. They were brought down together to the experimental rooms and they seemed equally weak physically. Kompa could barely walk; very much subdued she lay down, ate very slowly, would not jump on the stand as usual, was very sluggish in her movements, would not come when called nor jump for crackers, kept tail tucked, would not jump from the stand but had to be lifted down. The behavior of Kompa was much more subdued on this date even than it was in 1931 after the escape from the paddocks described above."

As seen from the protocols preceding the fight, immediately after the fight on the same day, and on the next day after the fight, as well as from the chart, the crs of Billy were only slightly diminished, and on the day after the fight about normal. But the cr activity of Kompa was markedly affected. The excitatory reflexes were reduced to 0, and the inhibition (M140) was also weakened; this inhibitory stimulus usually produced sleep but after the fight the onset of sleep was delayed, which delay was not attributable to the external inhibition of the painful effects ("distraction") because there was some sleep in the intervals between stimuli. In both the dogs there was only a slight change in the URs, i.e., the secretion to the food after the animal begins eating. On the 19 March Kompa was much better and more lively, she jumped on the table without assistance, but would not stand on her hind legs, as was her custom, for food. Her activity was still retarded, all the movements were slow and subdued, but she was in a better mood than on the day before; instead of tucking her tail she wagged it and even jumped up for food sometimes. On 21 March, Kompa was lively and playful as usual, jumping up and rolling over in play, etc., although there were still two open wounds; the others had closed (Table 4, fig. 6b).

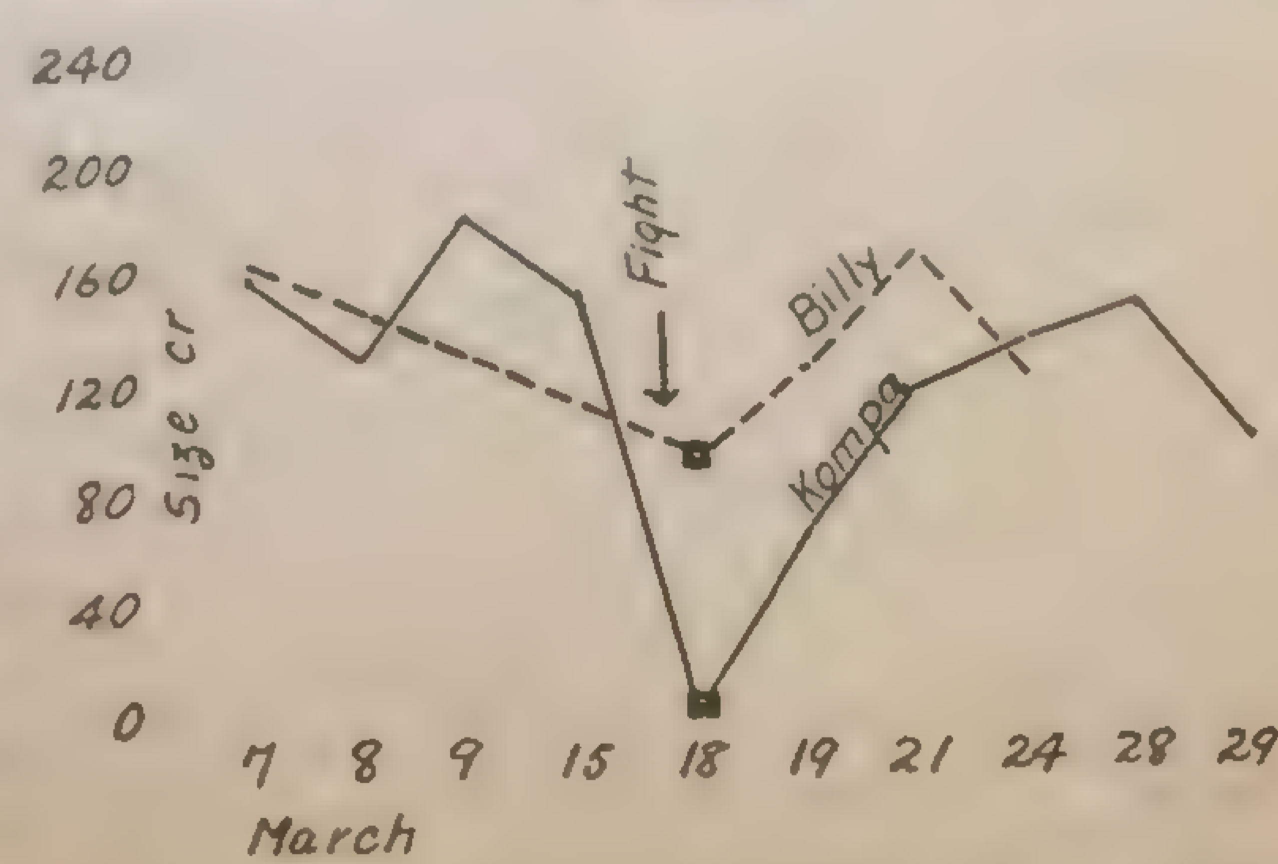

FIG. 6b. Effect of fight on crs in stable dog (Billy) and labile dog (Kompa). Cf. Table 21a.

The mere fact of fighting was not sufficient to cause the loss of balance in Kompa; for on 13 January Kompa killed a dog in her paddock, and the next day the conditional reflexes were normal.

Furthermore, this loss in the cr activity seems definitely attributable to the emotional strain of the fighting rather than to the pain *per se;* for I have noted in other animals that after many painful operations there is only a slight change

in the conditional reflex activity and emotional balance. For exampl... dog whose eye was enucleated on account of ophthalmitis on 22 April, ... a very slight drop in the conditional reflexes occurred even the da... operation.

The above animals showed also corresponding changes in their ... alcohol (*30*). Though the moderate doses had approximately the s... on all the dogs, the large doses caused more change in Kompa and Bl... Billy. No. 3 upon whom the alcohol had the most effect, was a patholog... having had part of the cortex removed from both hemispheres.

It is important to note that the relations between the crs are cha... nervous disturbances and that this is a much more reliable index than th... value of any one cr. Thus with Kompa the excitatory crs remained sta... inhibitory were destroyed; with Blue the strong crs were affected somet... the weak were unaltered.

In agreement with these natural experiences are the observations of ... made after the Leningrad flood and described as follows:

> The action of an exceedingly strong and unusual stimulation (for example th... 1924) on dogs with a weak nervous system, having a predominant inhibitory ... other words on a central nervous system with an increased tonus of inhibition, ... the etiology of a special traumatic neurosis. . . . In September 1924 a great flo... occurred in Petrograd afforded us the opportunity to observe in our dogs th... neuropathological disturbances which developed as a result of the extremely ... unusual external stimuli consequent on the flood. The kennels of the animals wh... on the ground at about a quarter of a mile from the main building of the laborat... flooded with water. During the terrific storm, amid the breaking of the waves ... ing water against the walls of the buildings and the noise of breaking and falling ... animals had to be quickly transferred by making them swim in little groups from the ... into the laboratory where they were kept on the first floor, huddled together indiscri... All this produced a strong and obvious inhibition in all the animals, since there was ... ing or quarrelling among them whatever, an otherwise usual occurrence when the ... kept together. After this experience some of the dogs on their return to the kennels ... no disturbance in their conditioned reflexes. Other dogs—those of the inh... suffered a functional disturbance of the cortical activities for a considerable per... as disclosed by experiments on their conditioned reflexes (*88*, pp. 344, 364).

Furthermore Pavlov could reproduce the effects of the shock experim...

> Then we adopted the following course. Our experiments with conditioned ... now usually conducted so that the dog remains alone in the experimental cham... the experimenter is seated outside the door in another room. From here the vario... are made to act on the dog: by a certain mechanical device the vessel of food is swung ... his nose, and here on the outside of the door are registered the results of the exper... Speransky sat quietly inside the room with the dog, but did nothing else, while I, ins...

him in the outer room, performed the experiment. The conditioned reflexes, to our great [illegible], reappeared, and the dog began to take the food. We restored the animal to his [illegible]. Next we tried the effect of a certain component, so to speak, of the [illegible] condition, by reproducing it in miniature. Under the door of the experimental chamber we allowed a stream of water to trickle. Perhaps the sound of the running water or its reflection threw the dog into the former pathological state. The conditioned reflexes vanished as before and their restoration had to be brought about by the means employed previously.

Moreover, when the dog had recovered, it was impossible to elicit an effect from the former strongest of all the conditioned stimuli, viz., the bell. It was inhibited itself, and afterwards there was inhibition of all the remaining conditioned reflexes. A year elapsed after the flood, and during this time we carefully protected the dog from every kind of extraordinary stimulus. Finally in the autumn (of 1925) we were able to get the old reflex, even to the bell. But after the very first time the reflex began gradually to decrease, although it was employed only once a day; and at last it disappeared entirely. At the same time all the remaining reflexes suffered, now temporarily vanishing, now passing into various hypnotic phases[2] ranging between the waking state and sleep although in this dog the latter state was never fully attained.

From all of these experiments it is evident that a variety of events accompanied by strong emotional upheavals can produce marked changes in the behavior of the animal. Moreover, this is characteristic for the individual animal, and it is observable not only in the general behavior and mood but can be more accurately measured by the changes in the absolute intensities of the conditional reflexes as well as in their relations to each other. Both the duration and the severity of the upset were closely *correlated with the type of animal*. In none of our dogs did this kind of upset last more than several weeks.

Thus in our three dogs of apparently different temperaments we meet with varying results as measured by the crs when subjected to similar severe emotional disturbances. Although the first episode occurred by accident we were able to duplicate the same effect in the corresponding dogs after an interval of seven months.

The fact that the changes depend upon individual peculiarities described as constitution or temperament or at least upon the individual gives experimental support to the emphasis laid by Hippocrates as well as by modern psychiatrists on the thorough study of the individual in preference to fitting cases into clear-cut diagnoses and well made theories; "nothing in psychobiology is absolute." (Adolf Meyer, *91*.)

The restrictions of the laboratory life may itself be a potent cause of nervous disturbance in dogs just as metropolitan culture is a great strain on the human being as is shown by the increase in psychoses in urban areas, as well as by the increase of irritability and other minor symptoms; although the laboratory life does not have an injurious physical effect on the dog, as can be seen from the instances

[2] Cf. with the paradoxical phase in Blue.

of dogs which have lived in the laboratory in health during experime… normal digestion as long as 12 years (Pavlov's dog) and several of my… are still healthy and working after 8 (Kompa, Sechs) to 13 (Nick) years… tory life.

However, simply bringing the animal to the confinement of the labo… impose a hardship upon its nervous system. In several of our animals… from the Virginia farm to the Baltimore laboratory, marked depressive… active symptoms have been seen. Thus Brenda, an American bull terrier… been raised by me from puppyhood, was kept on the farm until 4 months… she was brought to my house in Baltimore. Here, though with only a… (20 feet by 30 feet) in which to run, she appeared almost as normal… farm except for the fact that she would not come into the house; but wh… to the laboratory and put in a cage about 8 by 8 feet she showed marked… For 3 weeks she lay almost continually in one place in her cage, getting… to eat, drink, urinate and defecate. Even when brought out into the big… room she stood motionless as a statue, with legs akimbo, trembling, hea… tail tucked, completely unresponsive to my coaxing.

This immobility was so amazing that a collaborator (W. C. Hoffman… "You should have a movie of that dog. When you describe her in words… will be impressed nor understand how abnormal this dog was, standing… motionless with tail tucked and head hung for many minutes."

This dog never became normal in the laboratory, wasted away, refused… and finally died, after 4 months in a depressed state, although her ac… creased somewhat as seen in the chart (fig. 15). As the same cycle wa… on several occasions by removing Brenda back to the house and again to the… tory, it could not be considered a chance episode.

Although Brenda undoubtedly was a dog of psychopathologic constit… somewhat the same behavior has appeared in normal dogs. Thus a one-… male pointer brought from the same farm to the laboratory also showed a… reduction in activity but not the other pathological traits that Brenda di…

In both these dogs of the hypoactive type the laboratory caused gre… tivity. The noxious effect of the laboratory was not always in the direct… underactivity; for example, the neurotic animal Nick, an extremely hyp… type, always showed increasing activity when brought from the farm to the… tory. Evidently the direction of change in activity is a result of "constit…

Another instance similar to Brenda was brought to my attention by Dr. … After the death of his father, the bereaved pet dog would not leave the h… walks or exercise with other members of the family, remained constantly… former master's room, became more and more dejected, ate less and less… of choice food and coaxing, wasted away and after two months died.

As other examples of prolonged disturbed behavior outside the laborato…

following may be mentioned. A young cat in my home with her first litter of kittens a week old refused for four days to nurse them after a puppy had lain in the basket, and even spit when brought near them.

> One of my strong work horses was handled differently than he was accustomed to. He had always been driven by the reins and this time (for the same type of work) he was led by the bridle by a stranger. He instantly began to lather and to heave. On reverting to the former method of driving him, his breathing became normal and he stopped sweating.
>
> One of my cows has the habit of tossing her head up when she is eating dry feed, thus scattering part of the feed out of the trough. In order to make her eat dry feed with the head down I placed a broomstick a little above her head while feeding. Immediately she began to lacrimate while eating and gave $\frac{1}{4}$ less milk on the first milking, $\frac{1}{3}$ less on the second and $\frac{1}{2}$ less on the third and fourth milking. The lacrimation increased and on the third day she went off her feed and became so dangerously constipated that a heavy dose of Epsom salts was required. On letting her go back to her old habit of feeding, her droppings became normal and in two days she gave the usual amount of milk.[3] (Aluf de Ghize [*91*])

Though investigations are now being made on the effect of war conditions on different types of individuals, certain experiments simulating the explosions and fright of war have already been performed. The intercanine fights as well as the unkind treatment referred to previously reproduced some of the elements of war and battle. In addition dogs were subjected to loud explosions plus the fright and insecurity of being placed in a swinging hammock while in the experimental camera.

Details of the results obtained in three dogs will be given later under the accounts of Fritz, Peter and Nick (Ch. V). These dogs, who had been previously subjected to the strain of a difficult differentiation between food signals, had an extra load placed upon them by exploding firecrackers or shooting blank cartridges close to them in the closed camera. In two of them only a slight exacerbation of the nervous symptoms was observed. However, this change was only one of degree; the character and pattern of the pathological responses was unaltered. In the third dog, Nick, the symptoms were more aggravated than in the others. With all forms of stress the stable dogs have remained stable except temporarily.

In view of the fact that explosions and painful physical conditions imposed on the dogs apparently seemed much more severe than simply differentiating between two food signals, it is remarkable that the latter are yet more potent than violent physical causes in producing a breakdown.

The important fact is that the stable are always stable and the labile are always susceptible—a statement which will be amplified in Chapter VIII.

[3] I am indebted to Dr. Hugh Josephs for bringing this account to my notice. Although the disturbances were more in the nature of acute emotional changes than of chronic pathologic ones (neuroses), I cite them because of their interest as authentic extra-laboratory examples.

# IV. ACUTE OR FOCAL DISTURBANCES OF BEHAVIOR ARTIFICIALLY PRODUCED

IN CONTRAST to the traumatic neuroses and those arising from natur... shocks are disturbances which we see as a result of either 1) tensi... born reflex centers (functions, urges, drives), or 2) certain modifi... experiments begun under the rigid experimental environment of the l... the modifications may involve either order or intensity of the csi or the ... of th csi and USi as described in Chapter II. The space devoted to the de... of these various situations is determined by the amount of factual laborat... rial available rather than by the importance of the situation in ordinary l...

While any of the following methods may eventually result in a ch... turbance in susceptible dogs, in even the most stable dogs at least a tempor... results. On account of their universality as etiological causes of acute distu... I discuss these methods here in this category though it should be remembe... chronic disturbances ("neuroses") may sometimes follow.

Some of the symptoms described in the present chapter represent phase... development of a stereotyped, chronic neurosis. But it is not always true t... animal goes through the acute stage as described below in developing a c... neurosis, any more than it is true that in evolution a species has passed th... all the preceding lower forms of life that we know. Certain animals sh... symptoms for only a day or two and then recover, others pass through th... phase to a more serious and widespread involvement.

1. CONFLICT BETWEEN TWO CENTERS OF ACTIVITY OR DRIVES (URs)

Experiments based on a conflict between emotional drives were perf... Pavlov's laboratory by Yerofeyeva and by Konradi and Rikman. The f... vestigator in 1913 using a pain stimulus—a faradic shock to the skin—as ... food was able to transform this natural unconditional pain stimulus into appa... a pure food cs. However in spite of the fact that for a certain length of ti... animal gave only the food reaction to the painful skin stimulus, later it pass... an inhibitory and disturbed state during which all the other food crs were ... pressed.

About 1927 Konradi and Rikman performed the following experime... three UR "centers" or drives—two defense and the third food (*89*). One ... was made the signal for the introduction of acid into the mouth (salivary de... reflex), another tone an electric shock to the paw (motor defense reflex)... third tone a signal for food. The shock was sufficiently strong to produce m... defense reactions—tearing off apparatus, yelping, falling off the table, and ...

the motor defense reflex alone was evoked by any of the three tones with the suppression of the acid and food reflexes. By discontinuing working with the acid and the defense reflexes and reinforcing all the tones with the food reflex the behavior of the animal became quiet for several weeks, but after some months a pathological state set in. At this time the animal "fell into the hypnotic state, the equivocal or paradoxical phase ensued, and after feeding the defense reflex returned." Pavlov points to the analogy of clinical cases (war neuroses) in which traces of strong past experiences come out during hypnosis, giving as an explanation the retention in the subcortical centers of the past severe excitation with disorganization if there is weakened inhibitory action of the cortex or of the subcortex or if positive induction acts between the cortex and subcortex.

The procedures adopted by Maier (70) in rats and Masserman (73) in cats are chiefly in the nature of conflict between two different centers (drives), viz., between the excitation of food and of pain (fear of air blast).

A human patient suggesting a parallel to the animal conflict between defense and food unconditional reflexes has been observed in the Pediatric Clinic of the Johns Hopkins Hospital. An infant when two weeks old developed an esophageal stricture or obstruction for which a gastrostomy was performed. All the feeding was done via the stomach fistula until the age of 20 months. The obstruction was relieved shortly before this and feeding given through a nasal tube. Attempts to feed the child by mouth met with aggression and refusal for 3 to 4 months and have continued till the present though the child is two years old and though the tube is well tolerated. There was apparently set up here at an early age a conflict between two URs, defense and food, in which the defense reactions have become a cs for food, which is accepted only in the presence of the usual defense cs. It is quite possible too that lack of reenforcement of the natural conditional stimuli in oral feeding (after the first two weeks of life, when the child ate through the mouth) has resulted in a loss or weakening of the food crs necessary for taking food. The natural food csi have now become, from lack of reenforcement, inhibitory, leading to refusal; and, on the other hand, the US for defense is the food cs for nutriment introduced through the tube.

The part played by the qualities of food acting as csi can be easily seen from experiments with puppies to whom no meat was ever given till they were adults; they refused meat and could only with difficulty be taught to eat it. Stefansson, the Arctic explorer, related to me how his Eskimo dogs would almost starve before they would accept beef, fish or any food that they had not eaten as puppies; he was forced to supply them with polar bear, seal, wolf and other northern flesh. I have noticed in my own dogs that even the killers will never touch the flesh of other dogs.[1]

[1] On the other hand the selective feeding experiments of C. P. Richter on rats do show a universal

In the above examples two strong unconditional [illegible] were evoked simultaneously or in the same setting by food or destructive (pain) stimuli [illegible] an apparently similar situation (food vs. pain). Under natural conditions [illegible] kill its prey, but it does [illegible] when the animal goes forth to fight for and kill its prey, [illegible] It is not possible to analyze the difference between the two [illegible] but the following may be pointed out from the experimental point of view: the purpose of obtaining food is a [illegible] When the animal attacks for the purpose of obtaining food [illegible] motivation for food (tension in the food "center" according to Pavlov) [illegible] ful and furthermore the defense reflexes are of an active aggressive [illegible] free and uninhibited expression in contrast to the laboratory situation [illegible] passive, restrained, and usually unsuccessful defense. [illegible] patently and remarkably in one situation but not in the other. The [illegible] human being in the laboratory experiment is [illegible] and will be [illegible] a subsequent chapter. It may be a factor that deserves more attention than [illegible] given it.

The existence of any two URs simultaneously does not necessarily [illegible] conflict; this can be seen in the ordinary affairs of life as well as in the [illegible] experiments. The orienting or investigatory reflex is an unconditional reflex [illegible] with all new or strange stimuli; the result is the turn of the animal [illegible] source of the stimulus. This reflex frequently persists in some dogs in the [illegible] tory experiments even after hundreds of repetitions of the conditional [illegible] though after a few seconds it is followed by the appropriate food or defense conditional reflex. The persistence of the orienting reflex seems to indicate [illegible] animal with a weak nervous system, but I have never noticed any [illegible] resulting from the coincidence of the orienting reflex coinciding with [illegible] food or the defense unconditional reflexes.

In several dogs in our laboratory sexual URs have been elicited. The [illegible] reflex has never been seen to be in conflict with the sexual reflexes. [illegible] tions have been noted in one of our pathological animals, Nick, between sexual reflexes and anxiety producing stimuli, but these have not [illegible] nature of a conflict.

The failure of the conflict here could well be attributed to the weak [illegible] of the orienting reflex in comparison with the food, defense and sexual [illegible] or to the biological nature of the orienting reflex as a coordinating, [illegible] In the detailed account of Nick, these factors will be further analyzed.

[illegible]

Thus it can not be stated as a general principle that simultaneous excitation of two URs results in conflict, nor even that the defense and food reflexes as they may occur together under natural conditions, lead to a breakdown. As pointed out above, there is likely some additional element inherent in the laboratory situation, perhaps in the nature of frustration, or perhaps in the special function (teleology) of the orienting reflex. The difficulty of an explanation based wholly on "meaning" or teleology is that it cannot be relied upon for an explanation, for the animal as often appears meaningless as "meaningful." That phenomena proceed in a definite order is incontrovertible as is also the fact that when the order is perceived either by external or by internal observation (introspection) it can be rationalized and given a convenient meaning. If from such a concept of meaning a prediction is possible then it is useful. But neither in nature (as we have already recognized) nor in biology is it true as Candide had to learn the hard way "*que tout est necessairement pour le meilleure fin dans ce meilleur des mondes possibles.*"

Whatever the explanation the fact is indisputable.

On the other hand the conflicts between sexual drives and other impulses are not only recognized as the most frequent causes of imbalance in human society, but animal observations point to the same fact. The dominating role of the sexual reflexes is too well known to need amplification. To mention a single instance within my own experience—an otherwise docile bull who does not venture beyond a low wire fence to obtain food, will attempt to jump or break the strongest enclosure or even brave the hazard of an electric fence to get to a cow in estrus. The following experiments from one of our stable dogs (Vesal) and another labile one shows the imbalance in the crs concurrent with being placed next to a dog in estrus:

TABLE 5

DISTURBANCE PRODUCED BY PROXIMITY OF MALES TO FEMALE IN ESTRUS

| Dog | Date | | Control +cr | Control −cr | With Dog in Estrus +cr | With Dog in Estrus −cr |
|---|---|---|---|---|---|---|
| Vesal | 9 Feb.–17 Feb. 1942 | | 100 | 0 | | |
| | 18, 19, 20 Feb. 1942<br>21 Feb. 1942 | | 100 | 0 | 90 | 50 |
| Bamech | Nov. 1942 | Bu (strong cs) | 110 | | Bu 40 | (reversal normal relations) |
| | | M20 (weak cs) | 30 | | M20 120 | |

Two other male dogs in October 1942 when placed in a paddock with a dog in estrus were so disturbed when brought down to the experimental camera that it was impossible to work with them for about a week; the crs were abolished or

they became paradoxical, i.e., the weaker ones gave a larger effect [illegible] stronger (experiments of Dr. Dworkin, already cited in Chapter III).

In the discussion of acute disturbances are omitted situations described by Pavlov as external inhibition, or what we might ordinarily call distraction, [illegible] such an (unlearned) disturbance occurs apparently without conflict [illegible] the nervous system, in contrast to the situations involving internal [illegible] inhibition.

The process of simply forming the positive and negative crs in dogs [illegible] some disturbance of behavior. The animal passes through stages of [illegible] the new environment with more or less upset, finally reaching a stage [illegible] rium with appropriate reactions to each cs provided, first, the problem [illegible] difficult, and, second, the individual is a capable type. This disturbance [illegible] detectable in an analysis of the heart rates as will be pointed out in a later [illegible]

The USi most frequently used for the investigations of the crs of dogs [illegible] food or 2) pain, because of their biological importance as well as the [illegible] uring and recording some component of the reaction to these stimuli. [illegible] added recently by the author as a basis for forming crs is the sexual [illegible] interest as a comparative study and for special studies. Food and pain [illegible] remain the most useful in the ordinary laboratory study of general behavior.

In the work with dogs the disturbances of behavior are much more [illegible] established using food as the US than those using the kind of pain we [illegible] Direct physical pain as applied in the laboratory to both dogs and human [illegible] rarely gives rise to those marked disturbances of behavior occurring [illegible] an effect of conflict based on food excitation. But pain [illegible] produce severe upsets as pointed out in the chapter on traumatic neuroses.

It is probable that a greater disturbance of behavior is caused by [illegible] *defense and food* reflexes simultaneously than by using the pain stim[illegible] we seldom see in our dogs in which we elaborate only defense reflexes [illegible] disturbances that occur when both defense and food reflexes are [illegible] same setting.

These disturbances may be only acute or they may become fixed [illegible]

From all these considerations it is improbable that the excitation [illegible] centers and drives is responsible for conflict (as originally thought by [illegible] unless they are especially opposed to each other. That the mechanism [illegible] explanations are not so simple as it seemed to Pavlov is evident from [illegible] going examples. The whole problem requires further elucidation.

The question of what determines the intensity of the various em[illegible] is of much greater importance in ordinary life than in these laboratory exp[illegible]

[1] E.g., the pain of operations, as well as of the severe convulsions of shock therapy

for the reason that we usually work with only one or two different emotional states (food or pain) and that in normal animals the degree of emotional tension is controlled by the controlled intensity of hunger or the regulated intensity of painful stimuli. The maintenance of these tensions or states is essential for the production not only of neuroses but even of the normal cr. For example all the food salivary crs fall to zero when the dog is satiated, as well as the cardiac crs dependent upon the food (38).

### 2. Conflict of Conditional Excitation and Inhibition

In the routine training of dogs for the laboratory work with crs, the animal is put into the experimental camera about two or three weeks after making the salivary fistula, and fed there for a few minutes to an hour daily with intervals between feedings increasing from a fraction of a minute to several minutes. When he becomes quiet in the camera alone, without any one standing by him (as one does in the early period of experimentation), the salivary disc is applied, then the door is closed, and the cs is given 5 to 30 seconds before the food. After establishing a single stable positive cr, a period requiring one to several weeks or months, others may be added or a negative inhibitory cr established by introducing a cs unaccompanied by food. The negative cs, resembling as it does the positive, elicits positive motor and secretory responses at first but these gradually (after days or months) disappear. Differentiation by *analysis* has then occurred in addition to the *synthesis* when the animal forms the positive cr.

The procedure using painful, or in the objective terminology of Pavlov, destructive stimuli, is essentially the same except that the process is usually shortened, requiring only weeks instead of months. If we compare the motor with the salivary component of the food cr it is seen that the former is established much more quickly.[4] There is thus a marked difference in the expression through the skeletal musculature, controlled by the central nervous system, and through the secretory and possibly smooth muscle reactions, mediated through the autonomic nervous system. Furthermore the cardiac and respiratory crs differ from both the ordinary motor and the other autonomic cs.

In the routine work by the above methods with dogs chosen for general problems of the laboratory, those animals who are too unruly and do not adapt well to the environment are usually discarded. For this reason we have a selected group

[4] The shorter time for elaboration of the motor component of the food cr or for the motor defense cr, may be due to 1) the difference between the "learning" ability of the autonomic and of the central nervous system, and 2) to the method of measurement, viz., the stability of the secretory cr is measured quantitatively, while stability of motor cr is ordinarily a qualitative measure and much cruder—whether or not the movement appears.

of animals in our ordinary researches and therefore probably no fewer [illegible] than we would if we studied the whole canine population.

Our procedure in the training of the dogs is essentially the same as [illegible] in Pavlov's laboratory except that we restrain the animal less, having [illegible] about his neck to which a leash is fastened. He stands on a low table [illegible] the floor. In the Russian laboratories the dogs are frequently [illegible] harness under the fore and hind legs, and placed upon a high table, a [illegible] which at first adds to the disquietude of the dog.

The training may be roughly likened to that of education except that [illegible] tion to a certain amount of restraint, the conditions in the laboratory are [illegible] controlled and measured quantitatively in respect to the intensity of [illegible] (US) and of reaction (both UR and cr).

In working with the food conditional reflex the disturbances accompanying the restraint in the laboratory environment are gradually overcome [illegible] by the appropriate food excitation. Because the dog has become quiet and [illegible] well adapted to the laboratory environment before we begin any problem [illegible] ing our artificial inhibition (differentiation, extinction, or delayed cr), the [illegible] turbances in behavior which follow the introduction of inhibition can be [illegible] in my opinion, more particularly to the balance between excitation and [illegible] than to the restraint of the laboratory, although restraint *per se* may have [illegible] disturbing effects as shown in shifting some of my dogs from the [illegible] city. But the laboratory inhibition of the specific inhibitory cr is operative [illegible] tion to the restraint and separate from the restraint. This point deserves [illegible] because Maier and others have considered that the essence of the Pavlovian experiment may be restraint of the animal.

One great advantage of using the cr method for producing nervous disturbances in dogs is that we can see its development at every step and reproduce it [illegible] choose. It is perhaps of greater interest to know the *exact moment* and [illegible] under which a disturbance begins, and to understand *how* it spreads, than [illegible] hold the full-fledged neurosis. We may thus see the incipient stages [illegible] state of terminal psychopathology—something that we are unable to [illegible] clinic. In order to trace the disturbance resulting from the introduction of [illegible]

TABLE 6

inhibition from the very beginning, the following protocols from one of our first dogs[1] are submitted (Tables 6, 7).

TABLE 7
KOMPA 2 JAN. 1932
EFFECT OF CONFLICT

| | |
|---|---|
| 9:39 | M60(+) = 100 opposite stand given |
| 9:44 | M144(−) = 16 too close together |
| 9:47 | B(+) = [illegible] |
| 9:54 | Tactile Stim. = 4 |
| 9:59 | Bu = [illegible] |
| 10:[illegible] | L(+) = [illegible] |
| 10:34 | M60(+) = 3 |
| 10:44 | M60(+) = 9 |
| 10:49 | B(+) = 4 |
| 10:54 | Tactile Stim. = 1[illegible] |

A description of this animal was given previously in recounting the effect of the natural emotional upset on dogs (Ch. III) and the effect of alcohol on various types (*30*). She had been used in the laboratory since April 1930. The protocol (Table 6) for 15 December, 1931 shows the normal relations and reactions to the positive conditional stimuli and to the negative inhibitory one, M144. The latter normally produced sleep within 7 to 9 seconds after it was first started.

TABLE 8

| 15:28 | *M144*(−) = 65 |
| 15:33 | L(+) = 5 |
| 15:40 | Tactile Stim. = 1[illegible] |
| 15:46 | L(+) = 80 |
| 15:50 | *M144*(−) = 95 |
| 15:55 | L(+) = 5 |
| 16:00 | Tactile Stim. = 35 |
| 16:05 | $B_1$(+) = 95 |

Protocol 2 (Table 7) shows the result of giving M60 and M144, positive and negative csi, next to each other. The dog was more susceptible at this time than three weeks earlier on 15 December because she had *puppies* on 29 December which caused a temporary (for a few days) loss or imbalance of the crs. On 2 January M60 given at the beginning of the experiment is normal in size, but after M144 all the crs are decreased, and M60 in the seventh position at 10:34 gives only three scale divisions compared with 100 at 9:39. Ten minutes later at 10:44 M60 has recovered its strength somewhat. It is noteworthy on this day

[1] These experiments were performed by Harold G. Wolff and Gantt.

that there was poor differentiation between M60 and M144, and th ability to differentiate on that day may be considered as the cause of flict.

On 15 January, 1931 inhibition to M144 is better than on 2 Janu not so good as on 15 December. On 15 December M144 gave a seconds of thirty and eight for the two trials; on 2 January, it gave 15 January, 99 and 67 (perfect inhibition would be 0 secretion).

In Protocol 3 (Table 8) there is clearly seen again the effect of intr poorly differentiated cs on the subsequent crs. This is evident even on 15 ber when differentiation was fairly good. Bell coming next to M144 and 7 afterwards gives a secretion of 75 compared to 110 when it comes in th position 28 minutes after M144. M144, still poorly differentiated, has a effect on the strong auditory csi which follow it but a much more pronoun on the weaker and newer visual cs, L (light). When L follows M144 in 5 at 15:33 its value is down to 5, and 18 minutes after M144 at 15:46 its v 78. Exactly the same thing is seen when M144 is applied the third time at L coming 5 minutes later is duced to 5 (fig. 7a).

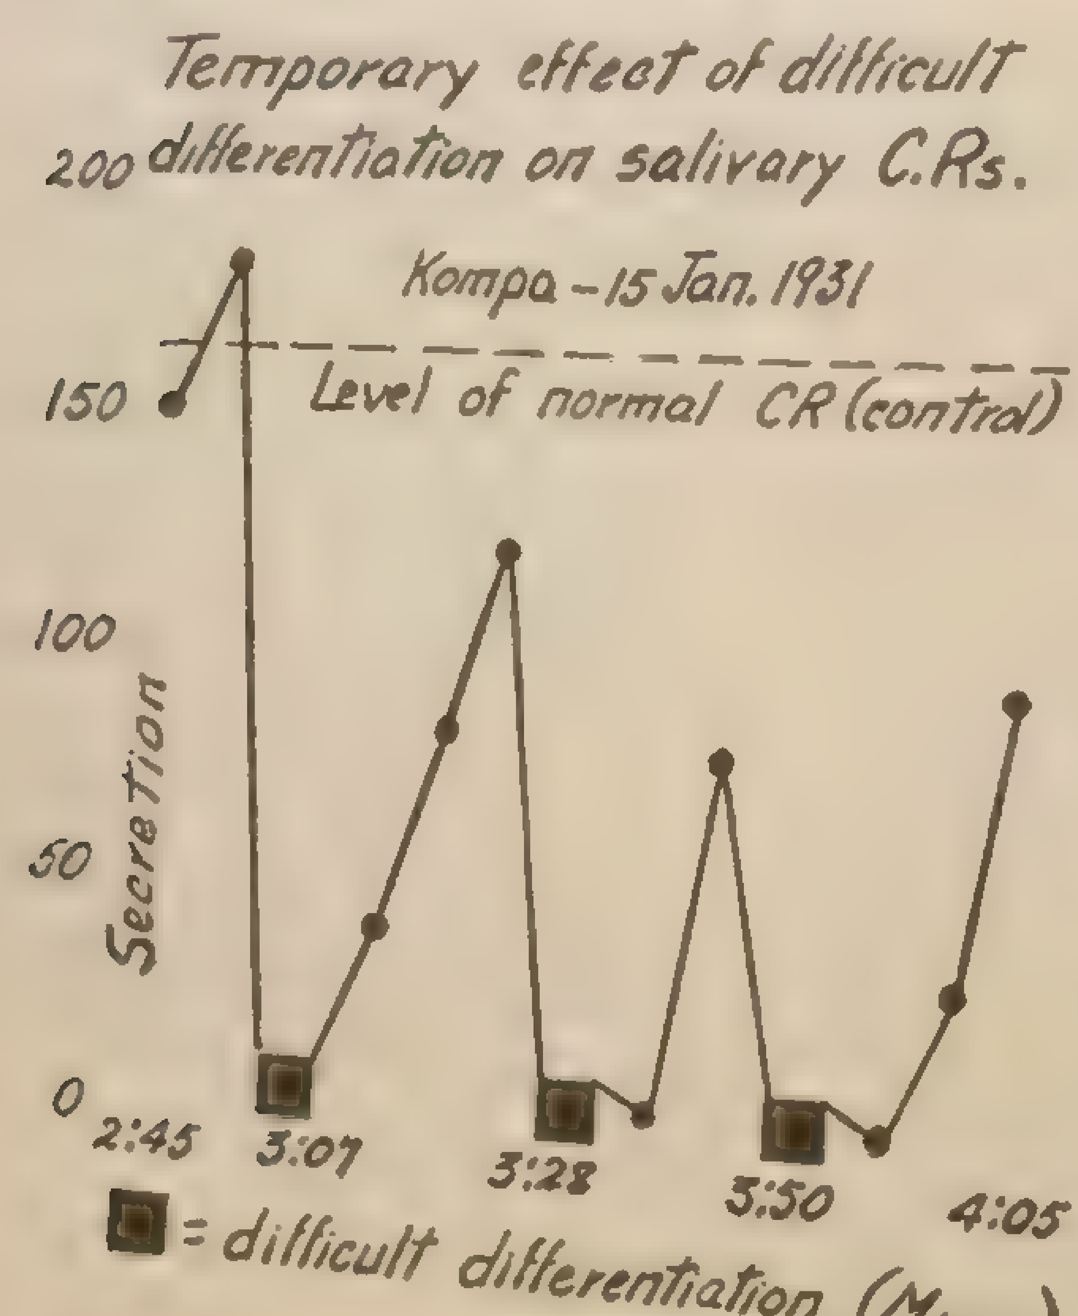

FIG. 7a

On 30 January the positive crs normal intensity and the inhibitory M144 is nearly perfect (with n tion for 10 seconds and only 13 minute). B gives 90 and 130, which was down in the experiment January to 9 just after M144, 110. But when M60, which had not used for several days, is introduced differentiation of it from M144 is shown by the secretion of only 3 in of a normal value of about 100, effect on the behavior is seen at on well as on the subsequent days. The mal does not eat the food on the stimulus, and on 31 January the disturbance is even more marked, as re both in the cr readings and in the general behavior. Differentiation to M14 impaired; instead of zero it gives for 60 seconds 113 the first time, 84 the sec and 292 the third time. Differentiation between M144 and M60 is practic lost; the values of the 10 second secretion to M60 is approximately the same to M144 for an equal period.

The behavior of the animal runs parallel to its ability to differentiate. O February differentiation to M144 is complete: there is little or no secretion

even though M60 is given repeatedly. Sleep appears within a few seconds after M144, and lasts during M144 and sometimes until the next cs. Restlessness and dyspnea have entirely disappeared. It is thus clear that by proper intervals between the cs (M60 and M144) and with continued practice this animal can handle the situation giving the appropriate secretion to each; she is quiet and without the nervous symptoms that we saw at the onset when M60 and M144 were given too close together in time before they had been differentiated.

These experiments are given in detail to show just how and where the breakdown begins. This animal was an excitatory and moderately labile type, as seen in these and various other experiments. From our knowledge of other animals we can state with assurance that, in a dog of this type, if the differentiation had been pushed[1] beyond the animal's capacity instead of in adjustment to its ability, a permanent breakdown such as we shall see in Nick would have resulted.

These exact and reproducible quantitative relations are a striking example of the applicability of the salivary cr method in the study of behavior. It affords us a quantitative measure for the difficulty confronting the animal before it is apparent in the behavior. By any other technic it would be difficult to detect the exact point at which pathological relations begin and to record them quantitatively. Moreover the ~~observable gross abnormal behavior is more~~ uncertain and often more difficult ~~both to observe and to evaluate. Needless to say,~~ the behavior is important as it alone is ultimately the criterion of the disturbance.

A comparable disturbance can be seen in the effect of a difficult differentiation on the motor defense crs, although the results can not be recorded in the same quantitative way. Thus in a stable animal, Connie, who had learned to differentiate perfectly between M92 (+) and M100 (—), when a closer differentiation between M96 (+) and M100 (—) was introduced, the result was a disturbance of even a simpler and an easier differentiation (M80 and M100) which was previously firmly established, without immediate disturbance in the behavior (fig. 7b).

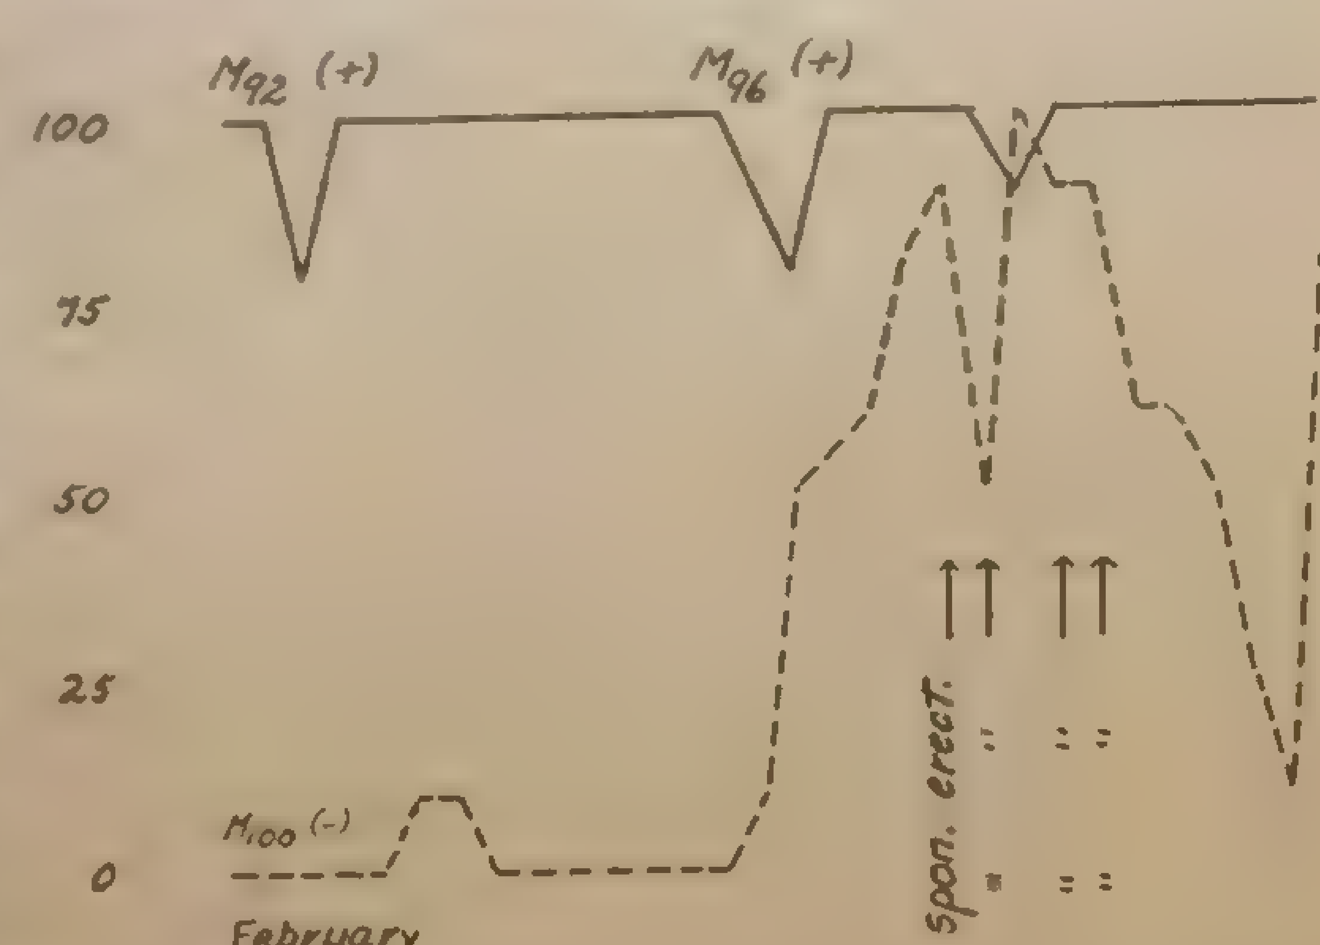

FIG. 7b. Concurrence of spontaneous sexual erections with difficult differentiation in dog C caused by changing M92 (+) to M96 (—).

[1] By "pushing" is meant repeatedly giving M60 and M144 close together or even at 5 minute intervals if they are not separated by a differentiated and non-conflicting conditioned stimulus, i.e., one not closely resembling physically the non-differentiated pair.

Even in this stable dog some weeks were necessary before the [illegible]
gave the correct cr to two metronomes which had previously been [illegible]
[illegible]ated. Moreover, during this period of difficult differentiation the [illegible]
to show other signs of disturbance in behavior, i.e., in the auto[illegible]
appearance of spontaneous sexual erections when put into the [illegible]
changed relations in the cr heart rates).[7]

Whether or not the animal would suffer a chronic disturbance fr[illegible]
flict of csi is also dependent upon the individual "constitution," [illegible]
see later. Some animals even though pushed with the conflicting stim[illegible]
never show more than a limited disturbance, without spread to the gen[illegible]
ity.

The above described examples show the burden imposed upon the [illegible]
system by a differentiation confronting the animal for the first time, in [illegible]
of elaborating crs. Likewise with well established crs we may have a [illegible]
space or time.

The term conflict is based upon the concept, for which there is some e[illegible]
that excitation and inhibition are mutually exclusive processes. When [illegible]
them close together in space the excitations must enter through the same [illegible]
and resemble each other in their physical properties so that they lead [illegible]
adjacent cortical areas. A conflict in space refers to the nature of the p[illegible]
negative csi, e.g., all metronomes of near M60 frequency stimulate cl[illegible]
receptor areas of the nervous system, or, if on the other hand, the same [illegible]
the brain is stimulated but the response is not the same—a "conflict in [illegible]
occurs. Even though they are not given together, and perhaps are separa[illegible]
days or months, their corresponding cortical regions may be supposed t[illegible]
so that one flows over into the other. That this view rests upon facts h[illegible]
shown by Pavlov in cortical extirpations of the skin analyzer. A conflict [illegible]
occurs when positive and negative csi are given simultaneously; e.g., when
([illegible]) is given at the same time or separated by a very short interval of s[illegible]
from a negative light or tactile cs, stimuli which come in over different rece[illegible]
The stimuli do not necessarily resemble each other physically nor stimulate [illegible]
lying receptor areas as M60 and M70 would, but there is a conflict in the ter[illegible]
or executor end only in that they lead to mutually exclusive responses. Fu[illegible]
investigations on the nature of the nervous conflict may give us a basis f[illegible]
satisfactory descriptive terms than "conflict in space or time"; the argumen[illegible]
their present use is that they are short and related to the experimental conc[illegible]
conflict.

Most of the laboratory disturbances are produced by this method. Fritz, [illegible]
and Nick are examples; they will be described in the next chapter.

[7] These phenomena will be discussed subsequently under the system changes.
[8] "Analyzer" is Pavlov's term for receptor system including the central brain portion.

### 3. Changes in the Established Routine

Although many of the situations under which a nervous breakdown occurs might be considered as changes in the established routine, I shall discuss in this section only those causative factors (especially those relating to the artificial crs) that seem to fall more naturally into this class than into the other groups.

Experiments showing that the dog adapts not only to the individual conditioned stimuli but to the order in which conditioned reflexes of varying intensity are given irrespective of the time element were performed by Gantt (*41*) in 1931 and by Kupalov (*89*, p. 99) in 1933. The adaptation to such an order of varying intensity is described by Pavlov (*89*) under the term "dynamic stereotypy."

In four dogs I used alternately large and small csi the sizes of which were determined by the amount of food reinforcing the conditional stimulus. The arrangement adopted here was one of the simplest conceivable—the regular alternation of two stimuli of different intensities. After many repetitions of the stimuli in the order *strong-weak-strong-weak* it was found that when one of the stimuli was repeated alone throughout the experiment, e.g., *strong-strong-strong-strong*, its value was dependent upon the relation of its position to the previously established order.

If the sequence was made more complicated and if no definite time relations were used to facilitate the establishment to the order, it was found that the value of the cs alone, rather than its position in the order of the experiment determined the intensity of the reaction. Kupalov, instead of using two positive crs of unequal intensity, adapted his dog to a simple alternation of excitatory and inhibitory csi.

Although adaptation is readily made to a *simple* order, I found that not only was it impossible to adapt accurately to a *complicated* order but that any adaptation was dependent upon the intelligence of the individual animal. A dog with part of its frontal, parietal, and occipital lobes removed on one side, although it could still elaborate positive and negative crs, showed no adaptation to the order in which they were given.

Although the adaptation to an established order is a powerful aid in the stability of the crs, on the other hand a change in such order may result in severe nervous disturbances lasting perhaps for months. One animal, in which a new stimulus was introduced into an established system of positive and negative csi, became extremely restless, struggling, barking, tearing off apparatus, with loss of positive conditional stimuli, refusal of food, and resistance to being brought into the experimental camera. This nervous disturbance lasted for 3 months. The animal returned to normal and the problem was simplified by reducing the number of inhibitory csi. Another detailed example is given in Chapter IV in our dog Kompa. On the basis of a conflict between the crs to the old and new patterns this is no more difficult to understand than is the production of a neurosis by a conflict between excitatory and inhibitory crs.

The human being also offers great resistance simply to a change [illegible] routine if the change is superimposed *from the outside*. The fact that [illegible] viduals do not conform well to the discipline of an imposed routine [illegible] contradictory to the general tendency of everyone to resist a change [illegible] from the outside rather than as a result of internal rhythms and [illegible] conformity to an imposed routine may well involve conflicts between [illegible] internal rhythms, if there are a large number (91, 95).

4. Change of Intensity of the Conditional Reflex

Before discussing the perverted relations, as measured by the [illegible] of various conditional reflexes, it is necessary to say something [illegible] intensities. The size, strength or intensity of the conditional reflex [illegible] several factors.

1. I have established the fact that the intensity of the cr, i.e., [illegible] secretion, varies exponentially with the unconditional stimulus, i.e., [illegible] of food, as mentioned in Chapter I (37).

2. In the early part of Pavlov's work it appeared that the [illegible] was related specifically to the analyzer of the cs. Olfactory and [illegible] tional stimuli were most powerful, next came the visual and the [illegible] the thermal. Later it appeared that this hierarchy was not [illegible] ample, a very strong light produced a larger cr than a very [illegible]

3. Within any given analyzer the cr is proportional to the [illegible] (as well as to the US) but only within certain limits. If the cs is [illegible] produce no greater effect than a weaker one, but on the contrary [illegible] gressively decreased effect. This is what Pavlov calls ultra[illegible] tion (56).

Conversely, the relation of intensities of the crs initiated through [illegible] receptors may serve as a measure for the disturbed cortical function. [illegible] scribes several phases through which the animal may pass—representing [illegible] degrees of disturbance of equilibrium between excitation and [illegible] 347, 355, 366). First, the phase of *equalization* in which all the [illegible] same intensity; second, the *paradoxical* phase in which the weak cs [illegible] positive effect and the strong csi become inhibitory; third, the [illegible] phase, during which all the crs to the usual positive csi drop out [illegible] other hand, inhibitory stimuli give a positive effect; finally, the [illegible] in which there are no positive crs. After this various pathological states [illegible] e.g., hypnosis, catalepsy. These have been fully described by Pavlov.

The appearance of the above phases may be used as measures of [illegible] librium resulting from various causes, traumatic, etc., as I have [illegible] III and elsewhere in this book. Such changed relations in the crs are [illegible]

delicate barometers of equilibrium than are the overt motility aberrations or ordinary observations of behavior. (See Chapter I and elsewhere in this book.)

5. Change in Relation between Conditional and Unconditional Reflexes: Lack of Reinforcement of Conditional Reflexes by the Unconditional Stimulus

Another type of change in the daily routine or pattern of the crs that may result in psychopathology is the failure to follow the cr by the usual US. A restless, agitated condition of the animal, either acute or chronic, may result. On the other hand, when the US routinely follows the cr, the animal is quiescent. There is a "refractory" period during which it is non-reactive to similar csi; but where the US does not follow, i.e., reinforce, the cr, the activity continues for some minutes or longer during the interval period when the animal should be at rest.[9]

This principle was accidentally discovered in the establishment of crs of different intensities by using a large and a small amount of food to produce a strong and a weak cr. The intensity of the cr was shown in these experiments to be logarithmically proportional to the amount of food used for reinforcement (*37*). Four dogs were used; in one pair, M20 was given as the conditional stimulus for 18 gms. and another auditory stimulus (air bubbling through water—Bu) was the signal (cs) for 3 gms. of food. In the second pair of dogs, in order to counteract the effect which each stimulus might have *per se*,[10] without reference to the accompanying food, on the size of the conditional reflex, the signals were reversed so that Bu was given with the large amount of food and M20 with the small.

Routinely the cs is given for 10″ before feeding and continued for 5″ after the animal begins eating; the cr is measured during the 10″ period; and the UR is *measured for 60″* from the time that the animal takes the food (practically from the moment the food is dropped in the box in front of the dog); as a rule, all the UR secretion is over however in 30″ to 40″, there being no more secretion until another cs is given. The length of the time required for the animal to eat 18 gms. of food is usually 5 to 20 seconds less than the period of the UR secretion (*37*). For the purposes of more accurate measurement the signal is given once daily for 30 seconds instead of the usual 10 seconds before food and the total quantity of cr secretion measured for 30 seconds. The UR is observed for a period of 60 seconds after eating begins although it is usually complete in 30 to 40 seconds. With 18 gms. of food, chewing lasts for 10-25 seconds depending upon the individual.

[9] This phenomenon was described by the author at the meeting of the American Psychopathic Association in 1932 under the title "A New Law of Inhibition; Inhibition of the Conditional Reflex by the Unconditional Reflex." As this paper has not yet been published in detail, the evidence for the law will be briefly described.

[10] Conditional reflexes vary in intensity according to the strength of the conditional stimulus as well as to the analyzer through which they come as mentioned previously.

The URs were also not directly proportional to the amount of [illegible] were in the ratio (2:6). It occurred to me that possibly the reason [illegible] were not directly proportional was because their true values mi[illegible] by the effect of the cr on the subsequent secretion. We know th[illegible] food may cause a secretion that lasts 60 seconds or more and it [illegible] to suppose that this cr would run concurrently with the UR and ad[illegible] i.e., show up in the 60 second period after eating begins.

This hypothesis was tested in the following way:

1. Measuring the secretion of saliva to the 3 grams and to the 18 [illegible] when eating was not preceded by the usual cs. This would not rule [illegible] the influence of the natural conditional reflexes, i.e., to the sight and [illegible] the food, operative for the fraction of a second between the time the [illegible] and when he begins eating. 2. Letting the cs run for a minute *aft[illegible] begins eating* and comparing the total secretion for the minute with the [illegible] obtained in the usual manner where the cs continues only 5 seconds [illegible] beginning of eating. If the cs has an effect it should increase the amount [illegible] for the total minute after the animal begins eating. 3. Comparing the [illegible] cr and UR secretion when they occur separately with the curve when [illegible] cide. 4. Preceding the large amount of food by the signal for the small [illegible] and vice versa. If the cr continues during the UR then the latter should [illegible] smaller when it follows a small cs and larger when it follows a large [illegible] ceding the US by an inhibitory stimulus, i.e., a signal which means "no f[illegible] the animal. This is a variation of the foregoing instance. If the cr is added [illegible] the UR the latter should be smaller when it follows a negative stimulus [illegible] sible role of induction has not been considered). 6. Comparing the curve [illegible] UR to food with that to acid when the former has been preceded by a [illegible] and, contrariwise, when acid is preceded by a food cs. If the URs are aff[illegible] the crs the curve of the cr should modify that of the UR.

Contrary to my hypothesis, I found that the UR in all the above instance[illegible] remarkably constant and apparently unaffected by the cs (signal) that pre[illegible]

About the same time Beritov (5) found that if the cs for a shock was rep[illegible] within a short interval of a previous shock there was no response to the con[illegible] stimulus. Beritov's and my experiments were done and published indep[illegible] and without the knowledge one of the other; furthermore mine concerns the [illegible] tory food system and Beritov's the motor defense. They are therefore st[illegible] confirmatory of the same basic law in more than one type of excitation.

Hence I conclude that the cr normally ceases its action the moment that th[illegible]

[11] Later I found that the unconditional reflex for a given food is nearly proportional to [illegible] of time required for the animal to eat the given quantity of food. Thus the animal eats the 3 [illegible] say 4 seconds and the 18 grams in 12 seconds.

begins, i.e., when the dog starts eating. But if the UR does not follow it at the usual time (the end of 10 seconds), the cr continues for a minute or more; hence one must conclude that the cr is cut short by the presence of food in the mouth, i.e., the US. The weaker, acquired, cortical reflexes to the distant signals (sound, sight of the food) give way, become checked by the more urgent, inborn, subcortical reflexes to the contact of food with the oral mucous membrane.

Summation is found both among allied (cortical) crs to signals, under certain circumstances, and also among allied segmental reflexes. In order for summation of crs to occur, they must not be maximal. If segmental reflexes are antagonistic instead of supplementary, see Sherrington's principle of the final common path, where one gains the right of way to the exclusion of the other. It appears that the relation of the cortical activity (cr) to its subcortical reflex (UR) obeys the same sort of law—as if the cr and UR were antagonistic instead of allied.

The implications of this law are many and important. Let us see what happens to a dog when the cs is not followed by the appropriate US. Suppose the animal has been trained to get the food 10 seconds after the signal begins: an activity of the animal's muscular and glandular systems is evident, increasing in intensity until the food is obtained, after a latent period of 1 to 6 seconds. Following the eating of the food the dog is quiescent until the next stimulus. But what is the chain of events when the food is not given after the cs? The activity directed toward the food increases for about 30 seconds, then the secretion gradually diminishes for a period of another 30-40 seconds, and the animal becomes restless, agitated, barking, whining, sometimes jumping about the stand, biting the attachments, trying to escape. If the cs is given only once without food the disturbance is not marked, but if given often one of several things may happen: the dog may pass again into a state of quiescence or sleep accompanying extinction, or into one of chronic agitation. In both instances cr secretion is usually though not always absent.

The element of time is not important; it is the variation of the time from the adopted procedure. For example we may elaborate a delayed cr in which the food is not administered until 3 minutes after the signal. During this period, the animal is quiescent and there is generally no secretion until the last 5 to 15 seconds before the food is accustomed to come.

In the chronically agitated animal where there is great restlessness but no secretion and even turning away from the food the same as in the defense reaction to pain, we may think that the cortical response has become permanently cut off from the appropriate subcortical reflex and diverted into other subcortical paths (defense) and diffused as a kind of general cortical excitability. However, this theory requires much more work for its verification.

When the cs is allowed to continue during the eating and even for 60 seconds

after the eating, one might think that this prolonged stimulus would
secretion again. However, the quiescent state (rest) initiated by the
US supervenes so that there is no reaction or secretion observable to the
refractory period (at least for the specific cs) ensues.

Whether this law applies also for other stimuli and other effect
question that requires investigation. In the measurement of heart rate
have made, as well as in the report of Miles (85), there is some evidence
not conclusive that the acceleration of heart rate accompanying the
sharp drop soon after the US, suggesting that the latter stimulus inh
crease in heart rate. Also following sexual excitation there is a long
nonreactivity or lowered responsiveness in most animals but especially
pathological dog to be described subsequently. In rutting females after
(unconditional reflex) there is a striking reduction or absence of the sexu
(conditional reflex?). C. M. Brooks has called my attention to the fact th
after ovulation (which is produced by coitus in these animals) will
for a certain period; this non-receptive state is not dependent upon
for the animal copulates freely later on during gravidity (53).

The explanation of the facts (inhibition of the cr by the US), th
upon a physiological mechanism which ends the act, may perhaps be
quately expressed as a behavioristic or philosophical concept such as ha
lined by D. M. Levy (70). He points out that the organism tends
an act as a unit, which is self-limiting. Physiological mechanisms as uri
defecation occur in units, as well as do the higher and more complex
behavior, e.g., battles or the performance of any task.

That the US automatically inhibits its own specific cr preceding it, may
sent the physiological mechanism upon which rests the more general
act as a unit.

The appearance of restlessness and agitation in the experimental situat
an accustomed US does not follow its cr (e.g., food by bell) furnishes a
the origin of anxiety. The relation of anxiety by Freud to coitus interr
frustration of a sexual nature, is clearly an instance of where the cr activ
followed by the appropriate and complete USi, and the onset of anxiety
closely analogous to the restlessness in the dog for several minutes w
for food does not follow the cs. The existence, however, of such a mechanis
upon food rather than upon sex would seem to extend the concept of an
involve other excitations than sexual.

As Whitehorn (91) has pointed out, a threat of whipping excites, but the
whipping releases this excitation. Under Nick's history the beneficial eff
giving painful stimuli is shown (Chapter VII). A somewhat similar

expressed by the British—"I'd rather be bombarded than bored"—where "bored" includes the anticipation of the act.

Frustration itself is not a sufficient explanation because while this might explain the failure of the food crs and the sexual crs, the motor defense crs are also inhibited by the appropriate US (pain), and in this instance instead of frustration there is relief from a noxious agent. An alternative explanation would be the persistence of a pattern according to the previous training. Although this consideration cannot be denied, the fact that the time elements, such as interval between csi, can be varied widely without destroying the pattern, although the omission of the US does change the pattern, this circumstance would argue for a factor other than pattern unless pattern be considered in a general way. Neither can the significance or meaning of the US be the determinant because, as mentioned above, a minute quantity of food will inhibit a very large cr.

# V. CHRONIC DISTURBANCES OF BEHAVIOR A[illegible] FICIALLY PRODUCED: CASE HISTORIES OF THREE DOGS

## 1. General Procedure and Synopsis

Beginning in 1931 three dogs were put through a training [illegible]
years) involving one or more difficult or impossible differentiati[illegible]
tones. Parallel studies were conducted throughout the life of these a[illegible]
them showed a disturbance of behavior in the situation of conflict bu[illegible]
degree; in one it was only temporary, in the second it was of long[illegible]
and more severe, and in the third there was in addition a spread to [illegible]
siological systems, suggesting the involvement of the "whole pers[illegible]
similar to a major psychosis, which continued until 1939. Since then [illegible]
a gradual amelioration of most symptoms has occurred, probably du[illegible]
factors in the treatment, but possibly also to other factors such as age.

In spite of the small number of animals in this study and the fact [illegible]
showed a somewhat different behavior under the same circumstances, [illegible]
scription appears worthwhile because of the mass of accumulated and [illegible]
material on three different dogs, with the evidence of "constitution[illegible]"
Furthermore there appeared in one dog a remarkable and clear-cut invol[illegible]
successive physiological systems, which as it *spread*, could be *traced* from [illegible]
of origin, time and again *reproduced* by reproducing the milieu, and finally [illegible]
after years of chronicity. Owing to the appearance of some of the sympt[illegible]
ticularly the sexual, in one of our dogs for the first time in the literature, [illegible]
account seems warranted as a starting point for further investigation. Obs[illegible]
even on single animals carefully made and repeated may give us valu[illegible]
mation.

*Fritz* was a police dog of apparently stable constitution, aged about [illegible]
when brought into the laboratory in 1931. On casual observation he app[illegible]
be a quiet, well trained animal of the watch-dog type. Sometimes he [illegible]
strangers who approached, but he was not otherwise aggressive. He was [illegible]
problems of differentiation, tactile and auditory. The auditory csi wer[illegible]
successively closer together until differentiation was impossible as with Nick[illegible]
behavior was only slightly disturbed; there was moderate restlessness, some[illegible]
ing, and shifting weight from one foot to the other. Most of the time the[illegible]
was quiet and ate the proffered food readily. All the nervous sympt[illegible]
pletely disappeared after a short rest.

The next dog, *Peter*, was put through a similar regime. Brought into the la[illegible]

tory in 1931, he appeared to be an active mongrel with the build of a beagle, about four years old. He was playful, though sometimes very irritable especially if touched near his tail. By ordinary observation he seemed moderately excitable. The behavior upset was intermediate between that of Fritz and Nick; it was much more pronounced than in Fritz, often approaching the restlessness and refusal of food seen in Nick. However Peter never showed the spread, the involvement of the other physiological systems ("whole personality") that Nick did; moreover his symptoms were confined to the camera and they disappeared after rest.

*Nick* was a mongrel male born about 1929 or 1930, weight about 12 kg. He was introduced into the laboratory in early 1931 and kept in the paddocks with the other dogs. For about a year before any work was done on him he was brought into the experimental room for casual observation. Nothing was noted then that impressed one as remarkable; in fact he was selected with Fritz and Peter for laboratory work, as being, according to general appearances, normal. He seemed to be lively and playful, perhaps even more companionable and easy to make friends with than other new dogs.

No careful and detailed examination was made on him prior to experimentation, but it is significant that casually and by the means of ordinary observation he *appeared* normal, as shown by selection for experiments requiring a normal animal. The contrast between the results of casual observation and the subjection to the rigidly controlled and delicate measurements in the routine of the laboratory deserves emphasis. *It is only by the latter method that we can detect the individual which will show a breakdown under stress.* The early symptoms seen in the laboratory situation which gave us a clue to the constitutional instability were in Nick, 1) refusing to eat, 2) the absence or inhibition of the conditional reflex when the differentiation became hard, the slight conditional reflex at first, and the easy setting in of inhibition, 3) the lack of differentiation, 4) the striking increase of muscular activity and restlessness.

It is remarkable in Nick not only that the nervous symptoms have continued for 10 years without repeating the original conflict but that the spread to the urinary and sexual systems did not occur till after 1935, several years after the conflict. That they were related to the conflict is shown by their appearance only in the experimental environment and other relationships to the original stimuli, as will be discussed.

Parallel experiments were done on the dogs (with certain variations as noted in the separate accounts) by Dr. R. B. Loucks for the study of irradiation, and it was in this period that the abnormalities began. Dr. Loucks' carefully controlled and painstaking original experiments from 1931 to 1935 are the basis for the account over that period.

A synopsis of the experimentation follows.

## COMPARISON OF FRITZ, PETER, AND N...

### FRITZ

B. about 1926. Male, German Shepherd. Wt. 21 kg.

1931

*May:* Brought to laboratory. Apparently stable, somewhat aggressive.

Parotid fistula operation.

Experimentation began June with T1130 as positive cs.

Secretory cr first appeared on 13th repetition; constant on 9th day after 30 repetitions.

T1130 used alone till 5 Aug.

No disturbed behavior in early training.

*5 Aug.:* Differentiated new tone without disturbance.

1932

*10 Feb.:* Partial deafness produced by destruction internal ear. Dog subsequently used for irradiation of tactile crs till 14 Mar., involving daily work and many differentiations of tactile si.

*14 Mar.:* Differentiation of 2 pairs of tones, one pair in ascending, other in descending order, viz. T530 and T420. Good differentiation by end June after 900 total repetitions of tones.

*9 Apr.:* Sexual activity normal.

*21 July:* Two other tones introduced and well differentiated.

*6 Oct.:* After 2 months' rest another differentiation of 2 pairs of tones closer together in pitch was tried but too difficult for good differentiation.

*Dec.:* Some restlessness (panting, shifting) but mostly quiet.

### PETER

B. about 1928. Male, Beagle T... 15 kg.

1931

*July:* Brought to laboratory. ... and sometimes irritable.

Parotid fistula operation.

cr elaborated to T1130; ap... trial and continued with ...

Quiet except for occasional b... ate food in camera.

*Aug:* Tactile cs introduced; cr ... 4 repetitions.

Inhibitory tactile csi introduced.

*Nov.:* cr to the tone became irreg... decreased in size from 40 to 1... more pronounced, some aversion t...

1932

*Mar.:* Differentiation of two pai... in ascending and descending order ... duced in Fritz; good differentiat... 1 month accomplished.

More difficult differentiations int... pronounced barking.

Peter now entered only with coaxin... quently jumping off the table, barking... ing, emitted fecal odor, sometimes r... to eat.

Some differentiation of 2 pairs of tone... 540 and 980 repetitions respectively ... positive and negative pairs. Peter now ... when salivary disc was applied, shook and struggled when it was replaced.

## COMPARISON OF FRITZ, PETER, AND NICK

### NICK

B. about 1929. Male mongrel. Wt. 12 kg. Playful, very active, apparently friendly.

1931

Brought into laboratory in 1931. Kept in paddock with other dogs.

1932

*Jan.:* Parotid fistula operation. Experimentation began. During preliminary adaptation to C, in first month somewhat restless—climbing, shifting about. Punished by experimenter on 4 Feb. for scratching off salivary disc.

*5 Feb.:* Refused several feedings. Did not refuse feeding again till 15 Feb. when first artificial stimulus was given (T1130); would not eat unless fed by hand.

*16 Feb.:* Terribly excited; did not eat till 2 or 3 min. after food was dropped; squealing; but quiet in interval between csi.

cr first appeared on 34th repetition.

In contrast to Peter and Fritz, Nick became very excited at beginning of elaboration of cr.

*Mar.:* Jerked head away from auditory cs as if avoiding pain.

*7 Apr.:* Differentiation attempted between a pair of ascending tones (T420-T530) and same tones in descending order (T530-T420). Forms weak secretory cr.

Fritz, Nick and Peter together in same paddock, Nick more retiring than others, especially when dog in estrus was in C.

*13 Apr.:* Nick began to turn away from food.

After 140 trials differentiation fairly good. In June after 300 repetitions of positive cr and 655 of negative cr, both motor and secretory differentiations.

*July:* Differentiation made more difficult.

During summer began to develop definite defense reactions, tearing disc from his face.

*Aug.:* Refused to eat food after positive csi. After rest from 27 Aug. to 10 Oct. Nick again readily ate food in C.

*10 Oct.:* Still more difficult differentiation introduced; after first day Nick refused food in C and continued to refuse it practically during his whole laboratory life until the present date (end of 1943), in spite of over 10,000 repetitions of cs and food.

Rations cut in half in order to stimulate eating in C; will eat in C only when fed by hand.

## FRITZ

### 1933

Good differentiation accomplished by March.

New tones still closer in pitch introduced; to this nearly impossible situation Fritz became non-reactive, continued to eat when food was dropped but whimpered and was restless (panting, barking, violent yelping or standing motionless).

Normal sexual activity in paddock. Motor cr disappeared but secretory cr present.

*June:* Fritz put in swing. Became quiet in swing after several months. Firecrackers exploded near dog in camera in Nov. Again became restless, but ate food whenever offered. About 5000 repetitions of cs were given.

### 1934

Complete rest from experimentation in paddock.

## PETER

### 1933

Nervous disturbance graduall[illegible] often could not be coaxed up [illegible]

*Apr.:* Impossible differentiation [illegible] restlessness greatly increased with [illegible] barking, marked trembling, [illegible] salivary disc, refusing to eat after fi[illegible] Had to be taken by force into C. W[illegible] food in antecamera. Ran in oppo[illegible] tion when told to jump on the sta[illegible]

*May:* Became quieter, would jump [illegible] after much coaxing, looked at food [illegible] quently refused to eat it. At[illegible] table or floor at end of experim[illegible] preferred to run out with food in [illegible] Barked when he ate ovals from th[illegible] antecamera ate normally. Often dr[illegible] barking furiously. Ate new kind [illegible] readily in C.

Small normal cr persisted to tones.

*June:* Became quieter, sleeping in [illegible] between crs.

*Aug. to Oct.:* Two months' rest.

Refused food in C; unimproved. R[illegible] tone 1024 continued till Nov. wi[illegible] 200 repetitions daily. Placed in sw[illegible] blank cartridges fired as with Fritz; [illegible] sulting antipathy to the C disapp[illegible] one month's rest though he still refus[illegible] during the experiment.

### 1934

After two months' rest, quieter [illegible] ate during experiment.

*May:* Experiments discontinued.

## NICK

1933 (continued)

[illegible] introduced. Shows great restlessness—prancing, turning head away [illegible] food dropped. Greedily eats food when released from table. [illegible] sulphide emanated from him in C. Refuses to eat from hand H.S., [illegible] R.B.L. After month's rest to 29 Nov. no improvement.

[illegible] 30 Nov.: no aggravation of disturbance.

[illegible] dog in C seemed to have a summating inhibitory effect on [illegible]. Definite pattern of hyperactivity when brought down from experi-[illegible].

1933

[illegible] rate in C 145; outside 120. Secretory crs have now all dropped to zero.

Drops food from mouth while outside C during activity of tone, but began eating about [illegible].

[illegible] with distance from tone.

[illegible] *Mar.:* Cinema made.

[illegible]: Refuses meat in C even with coaxing though eats it when put into mouth. Nega-[illegible]. Tones brought closer together.

[illegible] *Apr.:* 1 tone used throughout with random reenforcement; routine experimentation continued till 5 July, then discontinued till 1934.

[illegible]: Fumbles with food, dropping it from mouth.

[illegible] Blank cartridges fired in C near dog. Eats all of food in paddock. Sometimes closes [illegible] C but never sleeps. Marked trembling when blank cartridges were fired. Brings [illegible] from the C to the outside before eating.

1934

*Jan.:* Placed in hammock to increase nervous tension.

[illegible] Cortin given without improvement.

3 weeks' rest end Jan.; no improvement.

Routine experiments continued throughout Aug. Nick has been given 9335 repetitions of [illegible].

*August 1934 to July 1936:* Rest in laboratory paddock for 2 years.

## FRITZ

1935

Differentiation of tactile csi tried; ate food and gave positive secretory and positive motor crs.

1936

Rest in paddock.

1937

*2 Apr.:* Good retention of food crs. and differentiation. Defense reactions have disappeared; eats greedily from box.

1938

*May, June and July* used in study of alcohol on sexual reflexes. Quiet and cr activity in C normal. Died Nov. 1938, apparently from old age.

## PETER

1935

18 months' rest till Septem
much improved; quiet in C,
retained; ate food readily
of old and difficult csi (Tone,
about 5000 repetitions of food

1936

No return of nervous symptoms. 
ing in October.

## NICK

### 1935

Rest in laboratory paddocks. Excellent physical condition. Does not eat in C though eats greedily in paddock; no improvement when brought down to C.

### 1936

[illegible] measured in C: very small and irregular.

[illegible] *Oct.:* Until 18 May 1937 Nick fed whole daily ration of meat in C to transform painful into pleasurable environment.

Only slight and brief improvement resulting from above procedure. Spread of disturbance to involve respiration, urinary and sexual systems. Stereotyped pathological pollakiuria noted from now on. Great hyperactivity in experimental environment. Special type of respiration resembling asthma. Shows definite differentiation in behavior toward usual experimenter and others. Grovelling and fawning. Agitation increased somewhat by presence of other dogs in C. Reactions to former position of tone in contradistinction to actual present position.

*27 Nov.:* Normal sexual activity and somewhat quieter in C.

*16 Dec.:* Reciprocal relationship noted between sexual excitation and defense reaction—former inhibiting the latter, with gradual return of usual defense reactivity. Excessive pollakiuria.

*22 Dec.:* Normal sexual relation with dog in estrus; less anxiety for several weeks.

### 1937

*5 Jan.:* Activity record shows dog more quiescent after sexual excitation.

*15 Mar.:* Pathological generalization noted; rejects food formerly used in experiment, as well as meat during action of tone, but eats it a few minutes after cessation tone; definite time relation between action of tone and eating.

*20 May:* Sexual erection to metronome. Neutral visual stimulation made pathological by association with tone. Sexual erection becomes stereotyped in C.

*11 June:* Reciprocal relations between sexual excitation and anxiety; long refractory period of sexual excitation.

*June, July:* Experiments demonstrating that anxiety produced in C inhibits normal sexual excitation.

*1 Aug.-3 Oct.:* Rest on farm in Va. Negativism toward laboratory associate while on farm, but friendly toward strangers. Defense reaction toward laboratory food given on farm. Increased restlessness and pollakiuria with erection after painful experiences on farm.

*6 Oct.-11 Nov.:* Test in laboratory showed dog much improved by rest on farm, but former symptoms (panting, sexual erection, hyperactivity, restlessness) gradually return.

### 1938

*3 Jan.:* Former natural conditioned food reflexes, as well as artificial conditioned food reflexes, but not unconditioned food reflexes inhibited by C.

*12 Jan.:* Human social factor dispells anxiety; but not presence of other dog, even female dog formerly in estrus.

## NICK

### 1938 (Continued)

*7 Apr.:* Visual stimulus recently associated with pathological auditory stimuli ... elicit anxiety.

*From 17 May for about 1 year:* Effect alcohol tried on sexual reflexes: large ... other dogs inhibits sexual reflexes, but contrary to normal, there is increased ... on intervening days.

### 1939

*11 Jan.:* Progressive increase of anxiety as dog approaches C from a distance. De... tion noted toward members of families of those who worked with Nick in laborat...

Heart rates accelerated in C.

*Apr., May, June:* Conditioned sexual reflexes very difficult to elaborate to artifi...

*11 May:* Nick gives pathological reaction to verbal associations. Sexual erection ... kiuria continue. No improvement, but stereotyped pathological reactions have becom...

*25 Aug.:* Nick taken to farm in Va. for 17 months' rest. Fall in heart rate fr... laboratory to 110 on farm, few days after change. Heart rate markedly incre... approach on farm with appearance of other anxiety reactions. Nick's learning ... acute.

*12 Sept.:* Aggressive bulldog threatening Nick as well as cat clawing him caus... eration of heart than food or other associations of laboratory.

*Oct.:* Peculiar type of defecation, accompanied by erections.

*Dec.:* Urinates on food formerly used in laboratory.

### 1940

*Feb. Mar. and May:* Nick kept on leash on farm until summer. Friendly with farm... ant in contrast to attitude toward me. When I approach erection and ejaculation wi... lakiuria and increased heart rate. Also family association produces sexual erection. ... begins when person is 40 or 50 yards distant and increases as person approaches.

Allowed to run loose and accompany me during summer, Nick becomes more friendly ... is less restlessness and decreased pollakiuria. Becomes very loyal towards me, follow... devotedly around on farm, running after automobile, etc. Simultaneously becomes ... house, does not urinate there as formerly, lies contentedly at my feet.

*12 Oct.:* Presence H.S. on farm evokes urination and slight anxiety reactions, but less ... acceleration than when he was in laboratory.

### 1941

*14 Jan.:* Returned to laboratory. Prefers strangers to laboratory collaborators (W.H.G ... H.S.). 24 hour activity less than before sojourn on farm.

*16 Jan.:* Marked increase heart rate when H.S. passes in front of window moment... even with Nick in next room. Sexual erection, pollakiuria, and anxiety reaction ... toward personnel of laboratory, but less than before rest on farm.

*Feb.:* Erection when I reprimand him. Restlessness increased by bringing female in ... through adjourning room.

## NICK

[illegible] Normal sexual coitus, with inhibition food excitation by sexual excitation. [illegible] of human companion in C noted.

[illegible] effect of C on both anxiety reaction and normal sexual reflexes is much [illegible] on farm, though they still demonstrate influence of laboratory environment. Slight erections continue to appear in laboratory environment. Nearly all of the stereotyped [illegible] defense reactions are present when dog is taken to old laboratory environment, but to a lesser degree than formerly. Normal and unusually active coitus with dog in [illegible]. Physical condition has remained good. C has less inhibitory effect on sexual reflexes [illegible] on farm.

### 1942

Nick has been under observation 12 years, having had in this period over 10,000 repetitions [illegible]. For the past 8 years these csi have elicited the defense and not the original food [illegible]. He continues in good physical condition except for gastric hyperacidity.

[illegible] improvement by using former pathological csi as active csi for a shock on the leg; Nick forms these new crs fairly well. During this procedure there were no sexual erections—in contrast to their constant appearance in the old environment; also no pollakiuria. This [illegible] anxiety reactions to the specific signals but not to the total environment [illegible] the people most closely associated with him in the experiments, to whom he remains [illegible].

### 1943

Nick's condition continues improved. Even when returned into the old environment of [illegible] he shows much less of the original anxiety-like disturbances. The former manic-like [illegible] has diminished, spontaneous sexual erections have almost disappeared, though there [illegible] and the peculiar type of breathing. Nick continues to differentiate and to give fairly good performance in the experiments using defense reflexes instead of the food [illegible]. He shows a remarkable diminished sensitivity to the injection of adrenalin—even in [illegible] large enough to be fatal to normal dogs.

## 2. Case Histories

### [illegible]

A parotid fistula was made on 20 May, 1931. Fritz was accustomed to the experimental [illegible] feeding for a period of about four weeks before experimentation, the doors being [illegible]. In the early part of June a tone of 1130 cycles (T1130) was introduced as a [illegible] conditional stimulus. The secretory cr first appeared on the thirteenth repetition and [illegible] constant by the ninth day after thirty repetitions. Tone 1130 was used by itself as positive cs until 5 August, 1931. During this period there was no evidence of any disturbance of behavior, the animal standing quietly without ever barking or appearing restless [illegible] slight panting.

On 5 August differentiation of another tone was introduced for several days without [illegible].

On 17 August a problem of irradiation of inhibition arising from tactile csi was carried [illegible] this dog, without disturbance of behavior.

On 1[illegible] February, 1932, partial deafness was produced by destruction of the internal ear. (Operation by Dr. Walter Hughson.)

Daily experimentation with the tactile and the auditory (tone) csi was cont...
14 March, 1932. At this time Tone 1130 had been applied 700 times, when it ...
100 on the scale division for 10 seconds. On 14 March a differentiation of tw...
tones, one in ascending and the other in descending order, was begun. The nega...
T530 given for 1 second followed by a T420 for 18 seconds; the positive cs w...
Tones in reversed order, T420 given for 1 second and T530 given for 8½ ...
feeding, the two tones being separated by an interval of ½ second in each ...
sample protocol follows.

TABLE 9

Dog: Fritz

| Conditional Stimulus | | | | | Conditional Reflex | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Order of stim. | Time | cs. | No. repetitions | Durat. of measured cs. | L.P. secretory | L.P. motor | Size of secretion (cr) | Motor cr | Reinforced (US) |
| 1 | 10:32 | Tone 1[1] | 732 | 10 | 2 | 6 | 130 | + | + |
| 2 | 10:35 | Tone 2 | 57 | 20 | 10 | -- | 125 | − | − |
| 3 | 10:38 | Tone 2 | 58 | 20 | — | 4 | 0 | + | − |

| 10 | 11:01 | Tone 1 | 733 | 10 | 4? | 5 | 15 | + | + |

[1] Tone 1 = 1130 cycles; Tone 2 = 530 cycles (1″) followed in ½″ by 420 cycles for 8½″ or 18½″; To... cycles (1″) followed in ½″ by 530 cycles for 8½″ or 18½″.

During this period an opportunity arose for observing the effect of severe fightin... the presence of a rutting female in the same paddock with Fritz, and to compare this ... effect of fighting on other labile and stable dogs; and also to see the difference in the l... of Fritz and Nick in the same paddock. On the 26 and 29 of March, 1932, the cr to T1... was 195 and 150 respectively, and the UR 420 and 600. On 30 March it was see... Fritz had been wounded in a severe fight, having gashes about his head and eyes with ... swelling. He was with difficulty coaxed to come out of the paddock, showing reluct... leave the female. On 1 April the cr to T1130 had dropped to 75, the UR remaining 14... and 90 on the 6th, the UR being 475 on the 2nd and 310 on the 6th. There is thus ... to be not nearly so marked a disturbance in the cr activity in Fritz caused by the fight as ... was in Kompa and Blue; Fritz and Billy were both stable dogs showing about the ... disturbance. The female in estrus also produced less of an effect upon Fritz than it did ... other dogs, e.g., Bamech (q.v.).

The note on Fritz at that period stated: "8 March evidence of fighting over dog ... Fritz had deep tooth gashes about his head. In order to bring him out of paddock he ... be forcefully pulled away from dog in estrus which he was attempting to mount. Nick ... retreated to a corner by himself. 11 March, Fritz again very bloody and cut up; cou... be coaxed out of his paddock. It was seen that Fritz would viciously attack any dog ... came near the female in estrus. During same period, from 23 March to 9 April Nick's

T1120 varied from 30 to 90, and the UR from 100 to 185. Nick did not enter into the [illegible] nor was he seen to approach the dog in estrus, although the variation in his crs was as much as in Fritz."

Differentiation had become fairly well established by the end of June, after 600 repetitions of the negative chord and 300 of the positive:

On 21 July, 1932, a new differentiation between two other tones was started. Differentiation was complete by 26 August, 1932, the positive chord giving an average of 70 and the negative of 5, after the positive had been used 163 and the negative 327 times respectively.

On 6 October, 1932, after a rest of 2 months, another and closer combination of tones (represented in the protocols by T20-T21 positive and T21-T20 negative) was introduced. Slight differentiation was seen by 21 October after 65 and 140 trials of positive and negative respectively. Often there was non-reactivity on the cr (salivary) level (Table 10).

| 10 | 11:00 | A | 240 | 9 | 8 | 10 | + | + | 6[illegible] |

[2]Tone A (T20–T21) is a combination of two tones close together in pitch, T20 given for 1½ second and T21 for [illegible] seconds before feeding and 10 seconds after feeding.

Tone B (T21–T20) is the same stimulus as A except given in reverse order i.e., T21 for 1½ second followed by T20 for 19 seconds without feeding.

During December 1932 Fritz was occasionally very restless, but most of the time quiet. When the differentiation was good, instead of restlessness (panting and shifting weight from one foot to the other) there was drowsiness during the negative csi. Differentiation by 6 March, 1933, was manifested in both the motor and secretory latent period as well as in the salivary secretion (protocol 6 March).

As there was only slight disturbance to the above differentiation, two new tones of closer proximity were given. Although the animal was unable to differentiate, the behavior appeared undisturbed.

On 10 April, the two tones were replaced by tones of equal pitch, the first, 4th, 5th, 9th and 12th being reinforced, and the 2nd, 3rd, 6th, 7th, 8th, 10th, 11th unreinforced. To this practically impossible differentiation[3] Fritz became almost non-reactive during the arti-

[3]Differentiation by position is possible with simple alternation but very difficult with the above order. See Gantt, W. H.: Role of the Isolated Conditional Stimulus in the Integrated Response Pattern, and the Relation of Pattern Changes to Psychopathology, J. Gen. Psychol., vol. 123, pp. 3-16, 1940; also Chapter IV of this monograph.

food conditional stimulus (tone) though not to the stronger natural or [illegible] readily took the food as soon as it dropped.

The motor crs were absent but the secretory present.[1]

The typical behavior of the animal at this time was: with each conditional [illegible] whimpering, great restlessness, climbing on the food box, panting, barking, [illegible] yelping, though he never refused the food in the camera. Occasionally he stood [illegible] motionless during the cs.

At this time he was in the same paddock with a female in estrus. There [illegible] of the secretory reflexes, immediately after the experiment he tugged to return to [illegible] and there attempted to mount the female. The presence of the female apparently [illegible] his restlessness in the experimental camera. After the female was removed Fritz [illegible] Nick were put together in the same paddock.

FIG. 8. Fritz in 1938 listening to same tone as Nick in frontispiece and fig. 39. Shows normal orienting reflex (attitude of interest) without trace of former conflict.

Fritz was put into a [illegible] other two dogs, in June 1933 to [illegible] tension. His behavior became [illegible] after several months (in October 1933 [illegible] quently resting his head on the food [illegible] going to sleep.

On 8 November, 1933, firecrackers [illegible] exploded in the camera with the dog. He [illegible] became restless, panting, jumping about [illegible] telemeter experiments ([illegible]) [illegible] intensity of anger. The next day he [illegible] [illegible] from his face but continued to eat whenever food was offered.

In September 1935, after a rest of [illegible] months, Fritz was brought down and [illegible] a new routine, the differentiation of [illegible] stimuli. He continued to eat and give [illegible] positive secretory and motor crs. He was [illegible] in the camera again on 20 April, 1937, [illegible] a rest of 18 months. As a result of the [illegible] nervous symptoms and the defense [illegible] had almost completely disappeared; and [illegible] excellent retention of the food crs, [illegible] ferentiation of the positive cs (M2 [illegible] negative tone. The only trace of the [illegible] was slight agitation and panting to the negative tone. Throughout the experiment [illegible]

[1] This discrepancy regarding the durability of the crs belonging to different categories—secretory, respiratory, cardiac—has been observed in this laboratory on many occasions. E.g., [illegible] after a lapse of 18 months had completely forgotten with his locomotor and secretory systems [illegible] perfectly with the cardiac crs, i.e., showed no loss of the cardiac component of the formerly [illegible] food crs (experiments with M. [illegible]). The differences between different [illegible] generalize about human behavior on the basis of the study of only one kind of cr, e.g., food, or one [illegible] measure, e.g., secretory.

in good health. On 6 May, 1938, after 2 years' rest without interrupting [illegible], he [illegible] into the camera, gave a strong motor [illegible] toward the food box and ate greedily the food when it dropped into the box, showing spontaneous restoration of conditional [illegible] without trace of conflict. During May, June and July, 1938, he was used in the camera [illegible] comparative study with Nick of the [illegible] (see Ch. VI). His behavior was quiet and conditional reflex activity normal until his death in November 1938, probably from old age (12–13 years old).

Figs. [illegible] illustrate the contrasting behavior of Fritz and Nick in the same [illegible].

## 5. PETER

Experimentation began in July, 1931 by feeding the dog in the camera. A cr was elaborated to a tone of 1130 cycles; it was formed on the first trial and continued thereafter with some irregularity. During the first month the animal was quiet with occasional barking toward the end of the month. There was no refusal to eat. A sample protocol is shown below (Table 11).

TABLE 11

| [illegible] | Tone 1130 | 122 | 11–21 | 2 | ? | 58 | ? | food | 245 |

[a] [illegible] given 10 seconds before food and 10 seconds after food is dropped ([illegible]).
[b] [illegible] for 29 seconds instead of usual 10 seconds.

On 13 August the dog was put in the harness for the first time. A tactile stimulus was [illegible] with the tone. After 1 to 4 repetitions of the tone a positive cr was formed to two tactile stimuli and later differentiation was made to two others.

In November the cr to the tone became irregular and dropped from its previous value of 40 to 10. With the increase in difficulty of differentiation the barking also became more pronounced, and some aversion to food appeared; in December the animal frequently turned away from the food before eating it.

A study of irradiation of inhibition was carried out without imposing a special burden on the animal.

In March 1932 a differentiation of the two pairs of tones in ascending and descending order respectively was begun. The positive cs was the tone of 420 cycles followed immediately or with a very short pause by a tone of 530 cycles and the negative cs was tone 530 followed by tone 420. Differentiation was established toward the end of March 1932 (Table 12).

A second differentiation where the tones were somewhat closer together was introduced; the second months, differentiation was readily established. Toward the end of the year,

| 1[illegible]:3[illegible] | Tone 2 | 547 | 2[illegible] | 1 | 1 | 4[illegible]2 | [illegible] | [illegible] | [illegible] |

[7] Tone 1 = Tone 113[illegible].
[8] Tone 2 = Tone 53[illegible] for 1 sec. followed in ½ sec. by Tone 42[illegible] for 18½ [illegible]
[9] Tone 3 = Tone 42[illegible] for 1 sec., and after an interval of ½ sec. Tone 5[illegible] for 8½ [illegible] before food [illegible] 1[illegible] sec. after food (2[illegible] sec. altogether).

however, some disturbance of behavior was noted, such as barking when he w[illegible] alone and after eating as well as during the intervals—in spite of the good d[illegible] The animal now began to run away from the camera and would enter only w[illegible] he jumped off the table whenever he was not prevented. Barking and whining [illegible] frequent. A strong fecal odor was observed in the camera—also noted with N[illegible] dogs but not with Fritz when subjected to a nervous stress. Sometimes Peter [illegible] jumping down and running away.

The differentiation of an excitatory tone and a descending pair of closely [illegible]tory tones was continued, the tones being brought somewhat nearer together. T[illegible] differentiated after repeating the positive pair 540 times and the negative pair [illegible] However the nervous disturbance increased: the animal was more difficult to [illegible] camera, when the salivary disc was attached he howled and shook it off [illegible] was closed, struggled when it was replaced.

TABLE 13

Dog: Peter

Oc[illegible]

| Conditional Stimulus | | | | Conditional Reflex | | | | |
|---|---|---|---|---|---|---|---|---|
| Order of stim. | Time | cs | No. repetitions | L.P. (sec.) sec. | L.P. (sec.) mot. | Size secretion | Motor r[illegible] | [illegible] |
| 1 | 11:18 | A[10] | 32 | 1 | 4 | 165 | + | |
| 2 | 11:20 | B[11] | 67 | — | — | 0 | — | |
| 3 | 11:22 | B | 68 | — | ? | 0 | + | |
| 4 | 11:24 | B | 69 | — | 6 | 0 | + | |
| 5 | 11:26 | A | 33 | — | 6 | 0 | + | |
| 6 | 11:32 | A | 34 | 1½ | 5 | 110 | + | |
| 7 | 11:34 | B | 70 | 1 | — | 95 | — | |
| 8 | 11:36 | B | 71 | — | — | | — | |
| 9 | 11:38 | A | 35 | 2½ | 3 | 165 | + | |
| 10 | 11:40 | B | 72 | — | — | 0 | — | |

[10] A = T20–T21, i.e., two tones close together in pitch (not calibrated accurately), T20 given f[illegible] lowed by T21 for 9½ seconds before feeding and continued for 10 seconds after feeding.
[11] B = T21–T20, i.e., the same two tones in reversed order, T21 for ½ second followed by T20 for 19 s[illegible] not accompanied by food.

A more difficult differentiation was next established, while maintaining those which had already been formed. The nervous disturbance gradually increased: there was whining, crying, great resistance to attachment of the disc, barking; restlessness and incessant wagging of the tail. Sometimes he could not even with coaxing be induced to jump on the table which he formerly did eagerly.

Table 14 for 4 April shows that the positive crs which were irregular but still positive in October (Table 13) have now become uniformly inhibitory, so that the dog has neither positive secretory nor motor crs. In spite of the drop in the crs it is to be noted that the URs retain their former strength.

[12] C=T24–T25, i.e., two tones closer together in pitch than T20–T21 given in ascending order with feeding; D same two tones given in descending order without feeding.

On 10 April an impossible differentiation was introduced, i.e., giving the same tone (1024) twice in succession separated by a short pause and reenforced with food a certain number of times and failing to reenforce it at irregular times. Thereafter a great disturbance in the behavior resulted—terrific howling, barking, marked trembling; now the animal never could be coaxed up on the stand. Peter whined and howled when the disc was applied and almost immediately scratched it off. After the first stimulus each day he refused to eat. During the latter part of April he could not be coaxed beyond the door of the camera, and when he was put on the stand and the harness fastened he struggled violently, barked and whined. Later he would enter the camera after having been first fed some ovals outside, but when commanded to jump on the stand inside he would run in the opposite direction or crawl under the stand. Howling and barking increased, beginning even to the click of the switches for turning on the apparatus, an act which had been noted for several weeks. Panting, barking and whining would alternate with some quiet periods.

In May 1933 he became more quiet, and after about 10 minutes of coaxing would jump on the stand; but he barked furiously when the collar was attached, later becoming very quiet once the conditional stimuli were given. Frequently he looked at the food but would not eat it.

After the experiment Peter ate more readily, either from the hand or floor or table in the camera, though he often would take no more than 2 ovals and preferred to run out of the

camera to eat these. When coaxed to take the ovals from the table he would [illegible] and turn away barking. Outside the camera he would eat avidly. The behavior [illegible] in the camera even after the restraining harness and salivary disc were removed.

Toward the end of May it was seen that the animal did eat from the [illegible] had been put on leash, though he would often mouth the biscuits, drop them [illegible] ing (as Nick did) and bark furiously.

On 25 May even outside the camera Peter took the ovals in his mouth, [illegible] and barked loudly, or would bark violently when he was only offered the [illegible] brought near his mouth. Inside the camera he would look at the oval as it [illegible] away. When offered a different form of food outside the camera (purina [illegible] of Spratts ovals) he ate them readily. This reaction toward the two types of [illegible] dently due to the association of the food with the experiment, rather than to the [illegible] the food, as the dogs had no aversion to this food before it was used in this expe[illegible]

During this period there was still a small cr to both the reenforced and unre[illegible]

In June the animal gradually became more quiet and sometimes ate from the [illegible] though not during the experiment. On 23 June, he slept in the interval betwe[illegible] kept his head on the food box with eyes half closed. On 28 June, he was agitated an[illegible] ing, romped about the room, rapidly gulping several ovals. Refused to enter C. St[illegible] from flatus soon after entering C.

In order to investigate the changes in sugar tolerance it was attempted to int[illegible] emotional upset by putting the animal in a swing on the table and firing blank cart[illegible] the camera. Peter trembled but there was apparently no effect on his usual reactions.

The dog was given two months' rest from August to October 1933. When ret[illegible] the camera afterwards his behavior was about the same or worse; he refused f[illegible] camera although offered by hand, whining loudly when coaxed to eat or bursting i[illegible] and barks. On the floor of the camera he ate readily. Sometimes Peter could be persu[illegible] eat by forcibly pushing food into his mouth.

Occasionally the sight of the ovals placed before him would elicit furious barking. D[illegible] October the same marked fecal odor was noticed as previously when the dog went i[illegible] camera. Peter ate voraciously in the room outside the camera.

The repetition of T1024 was continued until 7 November, 1933, for over 30 [illegible] given many more daily repetitions than usual—routinely 60 and sometimes 200—at [illegible] intervals. Blank cartridges were fired near him in the closed camera, and at other times [illegible] fire-crackers were exploded. Although this procedure and the difficult differentiation [illegible] duced marked behavior disturbances while the dog was in the camera, a short rest [illegible] him to near normal. Thus when tested on 6 December, 1933, after a month's rest [illegible] promptly into the camera, jumping without hesitation on the table and eagerly [illegible] at first; during the experiment he refused food, but ate out of the food box without [illegible] when the door of the camera was open and someone was with him. After another re[illegible] two months—until 17 February, 1934—he was quieter and ate all the food in the cam[illegible] even after Tone 1024.

This dog was next given a rest of 19 months—until 13 September, 1935. On that [illegible]

and at intervals throughout the year his behavior was fairly quiet, there was little or no barking, no restlessness, he gave positive secretory food crs to the former csi, and usually promptly ate the food. Prolonged rest in this animal was evidently sufficient therapy to restore him to normal, in marked contrast to Nick. Peter was killed while fighting on 25 October, 1936, without showing in this interval a return of the nervous symptom.

### C. NICK

*1932*

Experimentation was begun on 5 February, 1932. The animal was accustomed to the camera by the usual procedure—food every 1 to 5 minutes for several weeks before giving any csi. Although no abnormal behavior had been noted in him previous to his being brought into the camera, during the first month of experimentation he appeared somewhat restless—climbing on the food box, and shifting about on the table.

Some clue to Nick's susceptibility to the experimenter was seen on 5 February, 1932, the second day after he had been brought into the camera and the salivary disc applied to measure the crs. On 4 February Nick was severely punished by a collaborator for scratching off the salivary disc from his face. On the 5 February he would accept only 4 feedings, although he had been eating readily up to this time. A note was then made as follows: "would not eat—probably afraid of experimenter for being so severely punished yesterday. Did eat biscuit outside camera."[15]

After this there was no disturbance in behavior nor refusal of food until 15 February when an artificial cs (T1130) was given for 10″ preceding each feeding. He would not eat until the camera was entered and he was fed by hand. On 16 February the following note was made (R.B.L.):

> Terribly excited by stimulus, turned to food but did not eat until entered and fed. Frantic twisting of head and neck. Whining sharply. Ate only 2 or 3 minutes after food dropped. Got so excited almost pulled collar off head. Squeals each time tone begins. Quiet in interval.

The cr first appeared on the 34th to 39th repetitions.

It is important to note that this animal became extremely restless at the first elaboration of the cs, and not only, as with Peter and Fritz, when there was a difficult differentiation.

Throughout February he was restless in the camera. Usually he would not eat during the cs—but about 40 seconds later. As soon as the cs started Nick whined and became restless, although he had been quiet in the intervals. Occasionally he whined also after the stimulus. When the laboratory assistant (H.S.) stood in the door, his presence started the dog eating immediately.

During March the positive cs was continued; sometimes the animal would jerk his head and bark. On 15 March he jerked up his head to the stimulus as if he were avoiding a blow. In the intervals between csi he was much quieter.

On 7 April, 1932, in addition to the positive cs (T1130) a pair of ascending tones (A = T420-T530) was made a positive cs and the same pair in descending sequence (B = T530-T420) was made inhibitory by nonreinforcement (Table 15).

[15] As a rule in this laboratory as well as in Pavlov's, dogs are never subjected to any physical punishment.

| 5 | 11:33 | A | 3 | +1 | $3\frac{1}{4}$ | — | 66 | — | — |
| 6 | 11:36 | A | 4 | +1 | $7\frac{1}{2}$ | — | | — | — |
| 7 | 11:39 | B | 2 | +1 | — | 2 | 5 | + | + |
| 8 | 11:42 | A | 5 | +1 | $9\frac{1}{2}$ | — | 1 | — | — |

[14] A = Tone 420 for 1 second followed by Tone 530 without food.
[15] B = Tone 530 for 1 second followed by Tone 420 with food.

From this protocol it is seen that Nick gave a weak cr to the T1130 and that h... food. Later, as will be seen, the secretory component of the food cr disappeared ent...

In the first part of April, Fritz and Nick were together in a paddock with a dog in es... A note on the behavior at that time showed that Fritz was very aggressive in attempt... mount the dog and in sexual overtures towards her, very reluctant to leave the padd... go to the camera, rushing back out of the camera to the paddock. When Fritz was ... observation in the paddock at times he did not show any tendency to fight, at other ti... he made a vicious attack on dogs who approached the female in estrus, becoming ... wounded. Opposed to the behavior of Fritz in this situation was that of Nick; he s... corner by himself, exhibiting no sexual activity while under observation. This was not ... ever a permanent characteristic of Nick; other times in his life he was seen to copulate acti... and effectively. However he exhibited throughout his life alternating episodes of a... and shyness.

On 13 April Nick was seen to turn (at the end of the negative csi) toward the door ... was in an opposite part of the room from the food box. In retrospect this act appeared as ... of the early elements of the conversion of the food reflex into the defense symptoms.

After about 140 trials, differentiation between the positive and negative combinati... tones was fairly good, and on 21 June after 300 repetitions of the positive and 655 ... negative csi, both the secretory and motor differentiation was established.

Thus on 21 June T(+) gave a secretion of 90, 65, 65, 35, 35, 35, 35, 35, 25 for t... successive readings, while T(—) gave zero secretion throughout. The dog ate all the ... offered. The corresponding URs were 230, 200, 160, 175, 180, 215, 205, 220, 145...

On 15 July a new combination of ascending and descending tones was introduc... which there was less difference in pitch between the two tones—therefore more difficult t... differentiate.

On the next day he jumped from the stand without eating; when put on the leash ... turned to the food but refused to eat until someone entered and coaxed him after whic... would eat immediately. When the food shelf dropped, making a slight click, he would ... his head away as if frightened. This action was the more remarkable as he had been star... for 48 hours. It was similar to that of Peter during the difficult differentiation.

Such behavior is evidence of the spread of the defense from its original focus about the negative conditional stimuli to include the positive as well. In keeping with the change of behavior—from the characteristic food reflexes to the avoiding, defense reactions—the cr's to the positive stimuli dropped to zero.

During this time he showed a gradual development of the defense reactions toward the negative stimuli: he turned away from the origin of the stimulus, looked toward the door, sometimes shook his head from side to side, sometimes restlessly looked all about the room, and then assumed a motionless position until the latter part of the stimulus, suggesting the panic expectation. Sometimes he tore the salivary disc from his face. Besides the avoiding reactions toward the negative stimulus, in August his ears were seen to tremble, he shifted his feet, trembled all over and "frowned." On 24 August he refused to eat to the positive cs when the food dropped in the box, although at the beginning and at the end of the experiment he ate greedily.

From 27 August until 10 October, 1932, Nick was given a rest with the result that after the 6 weeks' interval he readily ate all the food offered him as seen by the protocol for this day.

On 11 October a yet more difficult differentiation of two tones very close together in ascending (positive) and descending (negative) order was introduced. On the first day Nick ate the food given with the positive pair of tones, but on the next day he refused it and thereafter *for the next 8 years throughout practically his whole laboratory life he accepted no food in the experimental camera either with the positive or the negative conditional stimuli.* Up until this time while in the laboratory the dog had never been mistreated or subject to any activity except for the punishment referred to in February. Although other elements of the situation before this and subsequently may have contributed to the substitution of defense for food reflexes, there is strong evidence in Nick as in Fritz and Peter that the laboratory environment and the difficult differentiation was chiefly responsible for the breakdown.

On 11 October, 1932, the secretory cr to T20-T21 (+) was zero throughout, and also zero to T21-T20 (—). Compare this with the good differentiation on 21 June. The UR's on this day showed an average of 240, i.e., about the same as previously, illustrating the fact that there was no reduction in the physiological secretion of saliva.

The history from now on shows the comparison of the three dogs, and the persistence, development, and gradual involvement of many physiological systems as well as the stereotyped appearance of a train of symptoms in Nick.

In an attempt to increase the tension in the food center, and consequently the food reflexes, his daily ration outside the camera was halved, so that he received only 200 gms. of meat and 100 gms. of bread for several weeks. His reactions now, on the contrary (12 October), seemed to be continuously aggravated; he ate only from the hand and only after much coaxing; to the cs1 he backed away, shifted his weight from one foot to the other and on cessation of the tone he moved forward again, looking "anxiously" toward the door. A remnant of the food cr remained in the form of looking at the food box when he heard the food dropping, and licking his chops. There was also loud whimpering.

On 13 October two extraneous stimuli were introduced, a tactile stimulus on the skin, and the sound of a door bell. His defense reactions were now *generalized* not only to the

auditory stimuli but also to the tactile: during both of these he gave the same defen... tions as he had to the tones used previously for differentiation—prancing, turning of th... from the food box; when the cs stopped he whined slightly but sat on his haun... ceased his restless movements. He refused food even from the hand. When the old ... differentiation of the two tones was given without applying the salivary disc, the dog's ... havior was as much disturbed on this day as it was when the disc was on. That he was ... was shown by his eager hunt for food when he was released from the table. Having ... to eat in this way, he seemed to be dominated for a while by the food excitation; ... jumped on the stand and while on the table on the leash continued to eat 250 grams ... dog biscuit.

His nervous behavior was so marked at this time that he was demonstrated to th... His behavior remained about the same—eating outside the camera, but refusal of food d... some part of the procedure of hooking him up for the experiment, such as putting on ... salivary disc or his collar. Often a marked odor of hydrogen sulfide emanated from ... when in the camera. We have observed this in other dogs under conditions of strain. On ... October there was evidence of a spread of the defense reflexes not only to all csi and ... ing of the apparatus but even to being within the camera: he would not eat when en... free in the camera though he would look at the food box. Even when the doors were op... and H.S. entered he would not eat, whining more vehemently as the food dropped from H... hand into the box than he did in the intervals. On this day he could not be coaxed to ... the stand, although when a biscuit dropped on the floor, he quickly jumped down and gul... it. On other days, e.g., 29 November, 1932, he would eat when R.B.L. entered the cam...

He was given a month's *rest*, but with resumption of the experiment on 29 Novem... there was no improvement.

On 30 November his hind legs were put in a harness for the first time without ap... ciable change in his behavior, i.e., this added restraint did not aggravate the disturbance.

Frequently he would run to the camera without coaxing, jump up on the table and ... his tail.

At times (1, 3 December, 1932, et seq.) various steps in the preparation for the exp... ment seemed to have a summating influence in bringing out the defense reaction. O... December before the experiment he ate readily outside the camera, then ate 6 biscuits insi... and even 1 biscuit after the collar was attached to the leash, another biscuit hesitatingly ... the salivary disc was applied and even a few biscuits afterwards until the csi were given, a... which he started whimpering and refusing food. Conversely, on removing the attachm... at a certain stage he began to eat, but this seemed to be a continuation (irradiation?) ... defense reactions, just as there had been before the experiments of the food excitation, resul... ing in a changed threshold for some minutes after each excitation. Thus on 3 Decemb... after the experiment he would not eat after the salivary disc was removed, nor when t... straps were removed nor when the pneumograph was taken off, but only after the collar ... released; then he jumped on the floor and quickly ate 700 grams of dry dog biscuit.

Some years later a similar persistence of a state of excitation was seen in the rec... relations between sexual excitation and defense symptoms, described below as refract... period.

*1933*

The alternation of the positive and negative tone combinations was continued until 6 April, 1933, accompanied by the same behavior as seen previously. During this time the secretory cr remained at zero and the dog never accepted food during the cs.

In this dog as in some of Pavlov's animals, a slight additional stimulus would often dissipate the defense reflex and elicit the food reflexes. For example on 9 January, 1933, when Nick was placed on the stand as usual in the camera, he refused to eat, but readily took food in the same situation when the food was placed in an aluminum pan in the food box. He had been customarily fed from this same aluminum pan in the antecamera. On this day when the pan was removed, the negativistic behavior immediately supervened; the dog rejected food by pushing it out with his tongue. After the eating initiated by the pan had been transferred to feeding by hand or from the box, Nick refused to eat even out of the pan.

On the next day Nick would not eat out of the pan, but on other days the pan had the same effect as on 9 January. Pavlov reports in some of his neurotic dogs a removal of the paralysis seen in the so-called hypnotic states by some such simple procedure as we have seen here by using the aluminum pan.[16] Sometimes a slight change in presenting the food as breaking the biscuit up would initiate eating: this was similar to the removal of the hypnotic state by Pavlov's variation in feeding by heaping the food in little mounds.

The motor phenomena, however, in Nick were almost never of the hypoactive, paralytic type but consisted in marked hyperactivity.

On 13 January, 1933, Nick exhibited a type of restless behavior which was repeatedly seen thereafter when he was released from the apparatus; he jumped off the table, gobbled up the biscuit which he had dropped from his mouth on the floor, dashed in and out of the camera, sniffing under the table, jumping on the table a number of times, barking at the biscuit on the table without eating it. Though he looked into the food box, he turned sharply away refusing the food he saw there. Previously he would dash in and out of the camera, but on this day there appeared in addition for the first time the pattern of defense which recurred regularly thereafter for nine years as described later. On the table he shook himself violently, as he had often previously done when in harness to rid himself of the salivary disc, for which action he had been rebuked or punished by a slap because it dislocated the recording system. Loucks described this as a "chain pattern leading up to the release of the inhibition to a state where he eats."

The secretory cr was now always zero.

Blood was removed from Nick during this year for blood sugar determinations, with occasional injections of adrenalin, the results of which will be discussed in Chapter VI, section 1.

During this period pulse rates were taken (by palpation) in the paddock in the antecamera and in the camera by both H.S. and R.B.L. Generally even at this early period the pulse was *more rapid when taken by H.S.* The measure of cardiac rates by palpation during this period was therefore not as accurate as later when electrical records were taken. The results are tabulated in Chapter VI, section 4.

On 15 February, 1933, the *pulse* rate in antecamera, dog on floor, was before experiment

[16] See Pavlov (*89*) [under "hypnotism"].

87, 85 (R.B.L.); 87 (H.S.); near end of experiment dog in camera 90, 115 (R.B.L.) On the 15 February Nick ate from the food box still standing on the table ... leash was taken off.

During February Nick frequently ejected food placed in his mouth. The ... was frequently noted in the camera. A sample protocol on 1 March, 1933, ... was still zero, that he did not eat, and that his behavior was unchanged ... at floor, picking up crackers and dropping them, eating only at the end of the ... the camera he would begin eating only about 15 seconds after the tone).

TABLE 16

Dog: Nick

| Order | Time | CS | CR | | | Food | Behavior |
|---|---|---|---|---|---|---|---|
| | | | No. repetitions | Secretory | Motor | | |
| 1 | 11:17 | Tone A-B[17] | 574 | o | o | + | yelps and ... |
| 2 | 11:19 | Tone B-A | 673 | o | o | — | cries, backs ... |
| 3 | 11:21 | Tone B-A | 674 | o | o | — | cries, backs ... |
| 4 | 11:23 | Tone A-B | 575 | o | o | + | cries, backs ... refuses food ... |

[17] Tone A and B were very close together and could hardly be distinguished by the human ear. In ... *Tone A-B* tone A was given for ½ second, Tone B for 9½ seconds (at which time the food was dropped ...) continued for 19½ seconds. In the combination *Tone B-A* tone B was given for ½ second and ... seconds without food. The above procedure was repeated for 20 times daily and later on for ... 160 times daily.

The above stimuli were repeated in such order until 20 had been given. On this date ... the experiment when the dog was free on the floor of the camera eating biscuit, ... the tone was given he immediately dropped the food from his mouth, stood listening ... would not eat until the tone stopped. Also when taken outside the camera, a little ... from the tone, he dropped the food from his mouth as soon as the tone started, but ... up and dropped it again. He resumed eating about 15 seconds after cessation of the tone. This type of behavior (*stereotyped pattern*) could be demonstrated at will during the ... 6 years. Any auditory stimulus used in the camera would precipitate it. The inhibitory effect of the tone upon the act of eating and upon the food crs varied in intensity with the distance of the dog from the tone, a fact that could be demonstrated repeatedly.

During cinematographic recording of Nick on the 15 March, 1933, he showed no ... ticular reactions to the lights and the noise of the photographic apparatus, evidence that ... abnormal behavior is specifically related to those stimuli previously used in the camera rather than to *any* noise. Subsequently, the elaboration of a neutral stimulus (Light) into a ... one by association with the pathologic tone, is further proof of the specificity of the ... reactions in Nick, in spite of the spread to include closely related physical stimuli.

On 16 March, 1933, after the experiment, there was an attempt to coax the dog to ... meat out of the food box in the camera, but he turned definitely away. When the meat was put into his mouth he swallowed it and would eat a little from the hand but not from the food box. Further coaxing produced a negative reaction—the dog refused to take food ... the hand. Eating could be initiated again by holding his head in the food box close to the meat, when he would gobble it down rapidly, but he would not voluntarily continue eating

[illegible] food were held close to the meat in the box. He would not take the usual biscuit [illegible] hand or from the box until after he was released from the stand, when he jumped [illegible] and took a few biscuits with some hesitation and a suggestion of "ambivalence." *[illegible] that the effect of the meat, as well as that of the tone (noted previously), [illegible] relation to its distance from the dog.*[18]

After giving these two food tones—1003 repetitions for the negative and 765 for the positive—the pitches were approximated still closer so that it was impossible for the human ear to distinguish between the two. On 10 April, 1933, instead of using two tones of slightly different pitch, a pair of tones of 1024 cycles each was introduced and repeated at 1 minute intervals 20 to 60 times daily, reinforced by dropping food irregularly to some of the tones. This was of course an impossible differentiation, but as the dog refused food consistently, probably all of the tones acted similarly to produce the definite reactions. These tones were repeated 9335 times until 5 July, 1934, when the routine experiments on Nick were discontinued.

On 10 April it was noted that the dog was much worse when in the camera alone with the door shut, and that he became more quiet if one of the experimenters was in the room with him or the door was open. Whining began as soon as the door separating the dog from the experimenter was closed and it continued with intermittent howling, barking; it was accentuated by any one of the csi, during which he would suddenly back away from the source of the sound. When Nick was scolded in the antecamera, he would retreat into the camera and jump on the stand.

On 14 April, 1933, Nick began to pick up the biscuits and drop them from his mouth several times, running around frantically with them—described by R.B.L. as "fumbling." This became stereotyped and continued for many years whenever the dog was given ovals in the antecamera or in the camera.

On reducing the interval between csi from 2 minutes to 1 minute (24 April to the end of 1934), the above behavior was not aggravated.

In an attempt to study the blood sugar tolerance and to make the tension in this dog as great as possible, he was placed in a hammock (in the camera) which swung freely on the table next to the food box beginning 13 January, 1933, and continued daily for over a year to August, 1934.

On 15 June it was noted that Nick ate his meat in the paddock after he had returned from the experimental room as if his mouth were sore, i.e., he picked up the food, dropped it many times, similar to the fumbling with the biscuits seen in the antecamera.

On 19 June he refused to enter the camera, running away, and only after numerous commands was he induced to enter. During this month he also refused the oval biscuits in the antecamera, though he would eat other food, such as purina checkers or meat. This specific refusal of the food used in the camera is important because of the peculiar sexual reactions which this food elicited 6 and 7 years later in 1939 and 1940.

On 30 June in the camera his eyes were seen to be partly closed, although he was very alert. This was the nearest that he ever came to sleeping in the camera.

[18] Here and later with sexual reflexes it was repeatedly shown that there is an effect of distance suggesting the precision of what one usually sees in mechanics.

On 17 July and for some time afterwards, he would race madly about the [illegible] the ovals around in his mouth, pawing them, but sometimes eating them in the [illegible]

On 13 July, 1933, blank cartridges were fired in the camera near the [illegible] 13 July, 1933. On 20 July Nick jumped down from the swing, howling loudly [illegible] the first of four shots; and Nick repeated jumping down though he was replaced [illegible] This procedure seemed to increase his hyperactivity for the next few months [illegible] change the pattern of his reactions. Further abnormalities will be described [illegible] occur.

He was given a rest from 8 September to 6 October, 1933, without any impr[illegible] his condition. He still rushed madly about the room when the food was tossed [illegible] outside the camera with much fumbling; in the camera he whimpered and whi[illegible] food shelf was dropped. After the experiment he ate the ovals as usual but tossed [illegible] given purina checkers (a new food) he ate them without tossing or fumbling, [illegible] refused them inside the camera. Marked trembling of the body was noted. When [illegible] were fired there was terrific howling. When given checkers to eat inside the cam[illegible] bring them outside before eating them. On 28 October after being fed checkers [illegible] in the antecamera he also began to refuse these though not as consistently as he had [illegible] He was given a rest from 2 November until 6 December; after this he showed [illegible] excited behavior, fumbling of food, dashing in and out of the camera as he had [illegible] viously. On 26 January, 1934, he took one oval, but refused all ovals after the [illegible] had been attached.

## *1934*

After favorable reports on the use of cortin in diminishing anxiety-like overact[illegible] Tilson (*54*) in patients and Liddell (*71*) in sheep, we tried its effect on Nick.

On 25 January, 1934, 2 cc. cortin (Grollman's)[19] was given intraperitoneally. [illegible] the 26th 1 cc. was given at 8:00 at 16:00 and at 1:00 (night). When brought [illegible] camera after this he appeared unchanged, refusing food, howling, whining at the [illegible] sound, lying down on the floor and refusing to eat even when coaxed, though he wo[illegible] the ovals and drop them. He appeared more fearful than ever.

On 17 January 1 cc. cortin was given every 8 hours as on the 26th. The dog [illegible] definitely worse, retreating in the corner to the slightest sound, trembling and howling [illegible] released from the swing he kept crouching beneath the apron of the experimenter. [illegible] not as hyperactive as usual but was more easily frightened. There was reluctance [illegible] the camera before the experimenter—an unusual act for Nick.

When taken outside the experimental room, Nick ate the ovals readily and upstairs [illegible] the paddock he ate a half pan of ovals without any fumbling, continuing when [illegible] hissing sound of compressed air was made similar to the one in the experimental room [illegible] when he retreated. This as well as other experiments to come later definitely sho[illegible] effect of the total environment on the animal.

[19] The amount was calculated by Dr. Grollman to be the equivalent of the cortin that a normal [illegible] of Nick's size would produce in a day. Each cc. represented 50 units of cortin corresponding to [illegible] dog units per cc. of the available commercial preparations.

On 28 January 1 cc. cortin was repeated at 8 hour intervals. Again he ate the ovals near his paddock and while coming down on the elevator, but in the experimental room he slunk [illegible] stopping to listen every few moments and only after great delay ate one or two ovals. He turned his head wildly, whimpering and howling. After the experiment he again refused to leave the camera until the experimenter did. He ate a few ovals then with great fumbling and turning around before eating each oval. When carried back to his paddock he ate readily in the elevator and near his paddock, ceasing momentarily when the hissing sound was made. [illegible] and other behavior in the paddock seemed to be normal.

At the end of January he was given a rest for three weeks without change in his subsequent behavior. 20 February he whimpered and cried while the food box in the camera was being filled. For the next few days he did eat some ovals inside the camera and while in the hammock without much coaxing. Again on 13 March he ate both in and outside the camera but he refused to take the biscuit from the food box. On 3 April he jumped twice out of the hammock and had to be strapped in. On 6 April he ate an oval even during the tone.

*1936*

Nick was given a two year rest, from 5 July, 1934, until 31 July, 1936. During this time he was kept continuously in his paddock on the 6th floor with the other dogs, sometimes in a paddock to himself. He had no special contact with the experimenter except when the latter would go up to get the other dogs.

On 31 July, 1936, he ate the ovals readily in his paddock, sat quietly in the elevator when brought down, in contrast to his usual frantic movements, and even ate readily in the ante-room. When ordered into the camera he dashed excitedly about, finally bolted in and jumped on the table. He refused to eat, turning his head away when offered the ovals, but salivating copiously. This negativism is comparable to that seen in Pavlov's cataleptic dogs who gave a marked salivary cr, even drooling at the mouth, but became "as rigid as marble" and were unable to move the front part of the body nor to take the food at which they remained staring fixedly.

When Nick was taken out of the camera he ate ovals again eagerly in the experimental room, with however some fumbling. He became excited when ordered back into the camera. There he ate the ovals at first, but later refused them.

Nick was in excellent physical condition during all this time.

When brought down on the next day he fumbled with the ovals and became excited on the elevator and refused all ovals in the camera.

It is thus apparent that the two year rest in the laboratory caused only a slight temporary improvement when he was returned to the same experimental environment.

It was later shown, in 1942, that the Tone could be transformed also into a specific motor defense cr to a faradic shock.

After the long rest there was a transient return of the salivary cr to the Tone. Thus on 27 June, 1934, there was an average secretion of about 7 mm. during 10 seconds action of T1024, but on 31 July, 1936, after two years' absence from the laboratory the cr to the Tone was on the first 10 trials as follows: 33, 108, 54, 25, 1, 4, 2, 13, 0, 0. The food was refused and there was no motor cr on either day. This indicates that the cr showed some

[illegible] restoration after the rest but was quickly inhibited after [illegible] the dog was returned to the same environment.

In order to see if the same Tone could be transformed into a [illegible] for the [illegible] based upon defense instead of food (injection of acid into the mouth) [illegible] T1024 was given for 10 seconds and followed by 5 cc. of [illegible] HCl [illegible] the mouth through a mechanical apparatus with the dog in the [illegible] secretory cr appeared on 4 August, after 34 repetitions of the Tone followed by [illegible]

TABLE 17

| Date | Time | CR | | | | [illegible] |
|---|---|---|---|---|---|---|
| | | Tone | No. repetitions | Secretory | Motor | [illegible] |
| 5 Aug. '36 | 8:15 | T1024 | 42 | 130 | — | [illegible] |
| | 8:19 | T1024 | 43 | 150 | + | [illegible] |
| | 8:23 | T1024 | 44 | 230 | — | 5 cc. |
| | 8:28 | T1024 | 45 | 145 | + | 5 cc. |

Routine experiments using the csi for acid were discontinued after August [illegible] next two years he was used in the same experimental environment for [illegible] development of the neurosis in the various physiological systems and therap[illegible] as described below.

As possible factors to be considered in this extension of the nervous condi[illegible] following: one of the experimenters most intimately associated with Nick (R.B.L. [illegible] whom Nick was perhaps more friendly than with the other two (H.S., W.H.G. [illegible] more in August 1936; furthermore, H.S. who remained had fired the [illegible] Nick. Another factor to be mentioned was the bringing of a dog in estrus [illegible] with Nick in 1936—about the time that the pollakiuria became prominent. How[illegible] be pointed out subsequently, the dog in estrus seemed to have more of a [illegible] than the reverse. Though there is no substantial evidence that the above factors [illegible] sible for the subsequent development of various symptom complexes, they [illegible] unnoticed.

From 16 October, 1936, until 18 May, 1937, Nick was given nearly every [illegible] ration of meat in the experimental camera instead of in the paddock as previously, [illegible] rule no tones or any artificial signals or stimuli were given in the camera. The purp[illegible] feeding was to produce associations in the experimental environment conn[illegible] pleasurable excitation of an opposite nature to the conflict—eating food which he liked [illegible] he was in a state of hunger. The results of this type of therapy were disappointing. [illegible] of showing marked improvement, Nick developed in the succeeding months new path[illegible] abnormalities of behavior, with evidence of the spread of the disturbance to involve [illegible] physiological systems as respiratory, urinary and sexual neuroses, years after the origina[illegible] flict had been removed.

When brought down on 15 October, 1936, after a ten weeks' interval since the [illegible] perimentation, Nick seemed more excited than usual. The agitation began as he app[illegible] the room, coming down on the elevator. Inside the antecamera, though still outside [illegible]

[illegible], he dashed madly around, ignored the biscuits on the floor. He went into the camera [illegible] but ran out immediately. Food was refused until he got a certain distance away from the experimental room: he would not eat in the corridor nor on the elevator nor until he was returned to his paddock on the 6th floor where he ate meat and salmon readily but refused the Spratts ovals (experimental food).

At this time there was noted a peculiar type of respiration, which apparently developed during the rest period and was elicited by bringing him into the experimental environment [illegible]. This consisted of a loud, raucous breathing with quick inspiration and labored expiration. It was somewhat similar to that seen in the camera during the tone (see graphs Ch. VI) except that it was accompanied by a loud wheezing as if the animal were hoarse. It persisted from this time until the present (1942) whenever the dog was excited and particularly as he approached the experimental camera or anyone who had been associated with the experiments. When brought down from the paddock this loud, forced breathing would usually begin on the elevator and increase as the experimental room was approached, disappearing in reverse order. Although suggesting asthma, examination of the dog by an internist (Dr. Murray Fisher) showed that there was no true bronchial constriction except in the large bronchi, no typical rales, but an increased rate of breathing equivalent to a respiratory "[illegible]."

Nick usually ate the pan of meat in the camera, though he often had to be coaxed. Frequently he would dash in and out very excitedly, panting, jumping up and down upon the table before he would finally begin eating. Simply attaching the leash to him, although it in no way interfered with his eating, frequently caused him to stop eating as if mechanically; but he would resume when the leash was unhooked.

Although the Spratts ovals were routinely refused inside the camera, Nick took them when they were cracked up and mixed with the meat. On those days when he would not finish eating meat inside the camera, he quickly gulped it when just outside the camera in the experimental room.

Externally, his behavior during this period of daily feeding in the camera varied from being somewhat quieter than he had been to agitation and hyperactivity, equal or greater than that seen before 1936.

The description of the behavior on the days noted below is typical and includes the appearance of new symptoms. On 20 October can be seen the difference in his reaction to H.S., who worked with him most closely, and to W.H.G. Frequently therafter it was noted that he was more friendly towards strangers than toward those with whom he was more closely associated. On this day the unusual rapid panting and hoarse breathing broken with intervals of quiet breathing were pronounced. He grovelled about the feet of W.H.G., but retreated from H.S. He ran quickly into the camera without coaxing, jumped on the table and began eating the meat but stopped abruptly as soon as H.S. placed his hand on the leash as if to tie him. Attaching the collar caused him to stop eating for a few moments, after which he started up again rather readily.

On 28 October, 1936, the presence of another male dog, Billy, tied in the experimental room with him seemed to increase Nick's agitation. This factor should be taken into consideration in comparing the effect of the presence of human beings and of female dogs as

nated later. He ate his full pan of meat on this day very excitedly, ... camera, fumbling with his biscuit on the floor outside. Brought down ... Billy was no longer in this room, Nick was quiet, ate the ovals without ... had been previously fed in the morning. At 13:40-41 Nick ate the meat ravenously in the camera. Here was seen the inhi... of the specific tone, and also of other tones which had not been used, in inhibiting ... er even to meat when Nick was hungry.

Outside the camera on that day Nick alternately grovelled around the experime... or exhibited an erect aggressive reaction, with hair bristling, towards objects in ... which he urinated many times, immediately going from one object to the othe... of being whipped for so doing. En route to the experimental room he urinated se... in the elevator and in the corridors.

On 16 December, 1936, during a demonstration of this animal before several ... saw the reciprocal relations between the sexual reflexes and the anxiety state eli... tone. Brought down at 15:00 he was hyperactive, running in and out of the cam... refusing to remain inside unless coaxed. At that time there was a female ... room who had been given a convulsion by electrical shock resulting in expulsion of ...

[illegible] Nick became intensely interested in this pool of urine, sniffing over it and lapping [illegible]. When T1000 was given during this procedure Nick paid no attention to the tone, but [illegible] to sniff the urine. At 15:15 he took meat outside of the camera after coaxing; [illegible] inside. When T1000 or T500 was given he stopped eating immediately, [illegible] and then running slowly, though he was already outside the camera and [illegible] distance from the source of the tone. When T1000 was given with Nick [illegible] camera, he gave the typical reaction of looking in the corner, retreating and whining, [illegible] no attention to food in the pan under his nose. At 15:20 a female dog was brought [illegible] camera close to Nick, whose external genitalia he sniffed. T1000 given for 1½ [illegible] after he had begun to sniff the female was without effect on him—he gave none [illegible] anxiety reactions to the tone but continued sniffing. As soon as the female was removed [illegible] to react as usual to the tone. The failure of the tone to inhibit the sexual behavior [illegible] the female or toward the urine, while the tone readily inhibited the food reflex even [illegible] the food was in the mouth, was evidence of the greater intensity of the sexual reflex [illegible] compared with the food reflex.

At 15:30 Nick began urinating in the room and by 15:45 he was urinating almost every [illegible] on some object. When brought out of the camera Nick assumed an aggressive mas[illegible] attitude toward the female dogs, holding his head and ears up, trying to mount them; [illegible] he was easily cowed, crouching at the raising of my hand over him.

During the next few days (through 21 December) Nick was very agitated, refusing to [illegible] meat in the camera, but looking in the corner where the audiometer used to be, occasionally [illegible] away from this place. Frequent micturition was a feature on these days—11 times [illegible] the antecamera on 17 December, 12 times 18 December, 6 times 21 December, i.e., [illegible] every minute. On the 18th he appeared more excited when someone entered [illegible] camera, which had been noted occasionally previously. Inside the camera he licked at [illegible] meat but refused to eat it, though when it was put on the floor of the antecamera Nick took it intermittently, hesitating some moments before grabbing at the next morsel. He rushed around the room frantically, jumping up on W.H.G. but avoiding H.S. On the 21st [illegible] was slightly less agitated and ate a full pan of meat in the camera at intervals.

Having noted the inhibitory effect of sexual stimulation on the appearance of the anxiety [illegible] to the tone and its milieu, on 22 December, 1936, at 10:30 a small dog in estrus [illegible] into the paddock with Nick. Coitus followed immediately. At 13:30 Nick was brought into the antecamera for observations. He was markedly more quiet than he had been [illegible] some time; also he ran into the camera without coaxing, and ate a pan of meat. There was no urination in the experimental room. The little female was left in the cage with Nick [illegible] 5 January, 1937. During this whole period, when Nick was brought down into the [illegible] room, he was much quieter, there was less hyperactivity in running, he went [illegible] the camera more readily, ate the meat then without hesitation and urinated only twice [illegible] antecamera during the three month period. On December 31 we noted for the first time in several years that Nick did not pant nor breathe raucously in the camera.

*1937*

On 5 January, 1937, after the female had been removed from Nick's paddock the effect of the tone was tried again in order to see what improvement had resulted from the feeding

in the camera and particularly the presence of the female with him. The tone ... 10 seconds; during the first two seconds he continued eating, then stopped, ... fed after one minute ate a little and then stopped again. After this he would ... 15 minutes even when coaxed by W.H.G. Unleashed, he ran out of the camera ... around the room for about 30 seconds, running back into the camera and eating ... When the meat was taken away for 5 seconds, Nick finished it quickly when it was ...

Nick was decidedly improved on this day—he reacted to the tone, showing less ... than he had for several years. There was considerably less hyperactivity in the camera ... he was comparatively quiet. He ate the full pan of meat every day for several ... camera, and sometimes took Spratts ovals from the food box. Panting was diminished ... absent, he usually went into the camera without coaxing and there was practically ... tion in the antecamera. This improvement continued until 31 March, 1937. In ... neither rest nor feeding of meat in the camera had much effect upon the behavior ... it seems justifiable to conclude that the companionship of the female in his paddock ... responsible for this striking improvement. Further evidence in favor of this view ... viously demonstrated inhibiting of the anxiety by strong sexual stimulation.

The purpose of the above note is not for evaluation of the role of sexual stimulation ... anxiety, as the data of this experiment were not designed to this end, but simply to ... the reciprocal relations that exist between sexual excitation and the anxiety-like state ... animal.

The 24 hour *activity curves* for this period show that he was much quieter after ... with the dog in estrus.

The subsequent observations in Nick show that after removal of this dog from his ... he gradually returned to his former state of agitation and "anxiety" in the experimental environment.

On 31 March, 1937, the effect of the tone was again tried. In the presence of visitors ... he was hyperactive, running violently and panting. In keeping with his past behavior ... was much more friendly with the visitors than he was with H.S. who usually work... him and whom he avoided. Outside the camera he eagerly ate the Spratts ovals, when ... were thrown on the floor in the camera, or on the table and even from the food box, the... he refused to take the food after the leash was attached unless coaxed; even when in... into the mouth, he rejected the Spratts ovals, though he ate the meat readily. Loud ... box, as they were routinely during his training, Nick looked down toward the *former* p... of the tone for a moment and started whining even though the tone was not given, and ... not come from that position since 1934. He would not take even the meat for 3 ... after dropping of the ovals, which as usual he refused. It was thus apparent that ... the tone but many other elements in the environment in which it was given had ... equivalent to the tone in producing the anxiety. The reverse process of differentiation ... occurred in this dog; instead of a progressive adaptation to a specific stimulus as occurs ... mally, a *pathological generalization* has occurred so that any stimulus occurring in the en... vironment can now call out the anxiety state. The tone was turned on at 15:15, using a ... low intensity, and continued until 15:21. During its action the dog would not take the meat ...

[illegible] not even after it (at 15:22); however, when some of the meat was put into his mouth at this time, he ate it; given meat at 15:23 he took it readily; but ceased eating immediately when the tone was turned on at 15:20½, stopped his rapid breathing and panting to take 3 or 4 long deep inspirations. Although the tone was on for only 15 seconds he still refused to eat the meat two minutes later at 15:28; at 15:20 he would not eat the meat from the pan but did if it were introduced into his mouth. Even when the tone was very faint, Nick assumed his usual posture, whined slightly and started his characteristic slow deep respiration shown in the graph (see Ch. VI, section 3). At 15:35 Nick was coaxed to eat by putting meat into his mouth after which he began eating out of the pan, but when the tone was started at 15:35½ he stopped eating and spewed the food out of his mouth, standing with tucked tail. When at 15:39 for two minutes the tone was turned up from faint to loud he again changed his rate of breathing, started whining and backed off. One minute later there was forced and markedly raucous breathing and retching. The effect of the tone on changing the respiration and inhibiting the food reflexes continued for several minutes after the tone was cut off; he rejected the food even when it was put into his mouth at 15:42. The salivary disc was removed at 15:47. On first coming out of the camera he did not eat the meat, although he took it after two minutes. When the tone was turned on inside the camera at 15:49, although the dog was outside and about 10 feet away, he dropped the meat he had in his mouth, and slunk about the room in a crouching position. Later he ran into the camera, jumping on the table then down quickly, eating ovals from the floor and out of the pan. There was no urination in the antecamera on this day.

From this and other similar experiments it is evident that there is a definite spatial and temporal relation between the action of the tone and the behavior of the dog: the effect of the tone diminishes directly with the distance it is from the dog, as well as with the clapsed interval of time.

The above examination on 31 March shows that although there had been an improvement in Nick the tone was still an effective inhibitor of the food reflex, producing in its stead defense reflexes.

When tested again on 9 April Nick was fairly excited and hyperactive. He ate in the camera until put on the leash, then he stopped, though he continued eating when fed from the hand and also ate from the food box. When T1000 was given for 1 minute Nick stopped eating immediately, whined and looked toward the place whence the tone originally came. He would not eat for 10 minutes after the tone even though coaxed, but he began eating when taken out of the camera, slowing up as soon as the tone was given but not completely stopping unless he was brought near the door of the camera. While the tone was on (inside the camera), he would not stay in the camera. About 1 minute after cessation of the tone Nick started eating.

It was noted that the typical loud breathing suggesting asthma occurred in Nick not only in the experimental rooms but when anyone who worked with him approached his paddock. On 20 May, 1937, Nick was fairly quiet when brought into the antecamera, though he began to pant loudly when approached by W.H.G. As noted previously, he ate in the camera until put on the leash. Reaction to the tone that day was the typical one. In order to determine the spread to other neutral stimuli, a metronome and a bell were given separately. To these he

reacted exactly the same as to the tone and in addition there [illegible]
in tremor.

An attempt was made to determine how far the pathological generalization [illegible] and whether it involved other analyzers besides the auditory. As the dog had [illegible] conditioned to any visual stimuli, a flashing light was tried on 9 April, 193[illegible] first no reaction except the orienting, which is a natural response to any new [illegible] ever on repeating it several times 5 seconds before the tone and [illegible] with the tone, the tone lasting for 10 seconds, on the 8th trial the light [illegible] value as the tone in producing the defense reaction. The effect of the light [illegible] subsequent days; it was seen to be not so stable as the tone and auditory [illegible] fairly easily extinguished but quickly re-acquiring the ability to produce [illegible] several times with any of the auditory stimuli. Thus on 20 May, 1937, the [illegible] first used produced only the orienting reflex, although on that day the [illegible] were equivalent to the tone. It is evident from looking at the respiratory [illegible] the light has nearly the same effect as the auditory stimuli, not only on the [illegible] upon the movements of respiration. (See Ch. VI, section 3.)

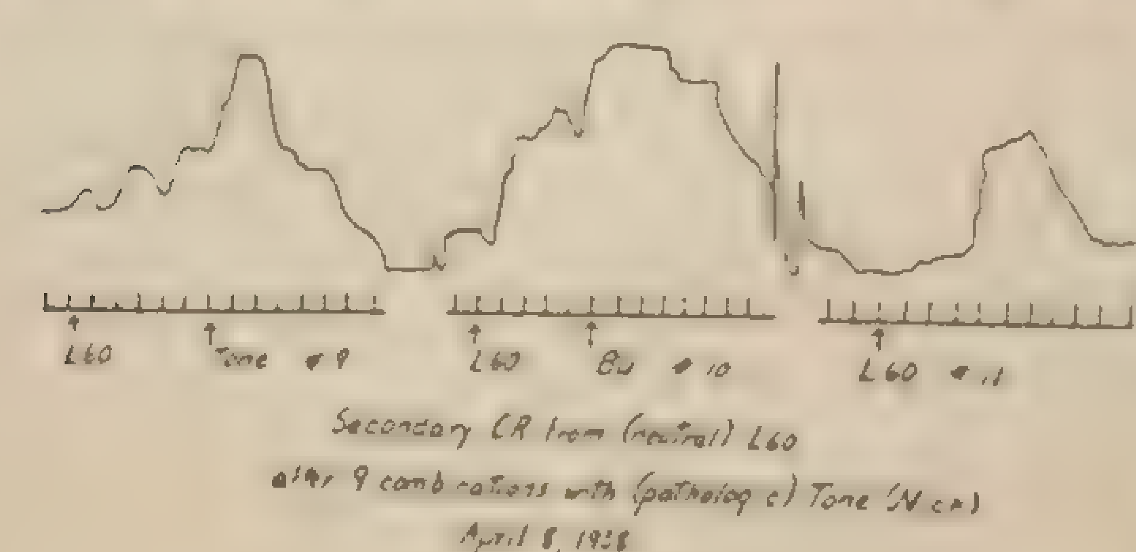

Fig. 9.

As I have pointed out, [illegible] period of the routine [illegible] flicting stimuli, and for [illegible] there arose, as it were [illegible] neuroses, indicating a spread of the [illegible] cal state to involve new [illegible] At first there were [illegible] the specific cs, then to [illegible] within the same analyzer, and [illegible] responses to any cs occurring in the experimental milieu. Next, [illegible] were elaborated in physiological systems not previously affected. The [illegible] neuroses have been mentioned. About this period there appeared [illegible] *of another system—the sexual.* The sexual symptoms took their place [illegible] sity, and perverse stability along with the respiratory and urinary [illegible] reciprocal relations existed, one side of which have been noted in the [illegible] estrus on the defense reflexes, and now the other side of the reciprocity [illegible] of the anxiety state to elicit sexual erections.

These urinary, sexual and respiratory neuroses lasted with some [illegible] next five years.

The reciprocal relations between the anxiety-like state and sexual [illegible] brought out in a series of experiments, to be described in more detail later. [illegible] apparent from the experiments of 10 June, 1937, when it is seen that [illegible] accompanied the anxiety, quickly appearing to the tone, and that on the [illegible] normally produced sexual excitation, there is a latent period of 1[illegible] onset of the excitation during which the stimuli that had habitually [illegible] completely ineffectual. This refractory period following sexual [illegible] animal is immune from the anxiety—passes off gradually. Thus 1 [illegible]

[illegible] excitation there is no reaction whatever to the tone; 6 minutes afterwards the dog [illegible] by turning his head but does not shift his position; after an interval of 13 minutes [illegible] only a slight defense reaction, and after 42 minutes the tone brings out a moderately [illegible] with slight whining (fig. 43).

The [illegible] relations noted above were seen in the same stereotyped form so many [illegible] that they could be demonstrated at will.

"Today as well as on previous occasions Nick was seen to react defensively when I tell H.S. '[illegible] Harry, give it' (referring to T). Nick also gives very slight defense (orientation [illegible] ears and backing slightly) to a faint T from three rooms farther up hall (doors [illegible])." (Note in June, 1937)

Nick was used for a comparative study of the effect of the experimental environment of [illegible] on normal sexual excitation from June until August 1937. The results of these [illegible] will be outlined separately in the next chapter.

In order to determine the effect of a complete change of environment, it was decided to [illegible] Nick not only from the laboratory but to give him a life of less restriction on a farm. [illegible] attempts to convert the laboratory environment—by rest, cessation of the experiments, and substituting for the conflict a strong food excitation (eating all of his daily food [illegible] experimental camera)—had only a slight ameliorating effect. Accordingly, 1 August, 1937 he was transported by train 200 miles out of Baltimore to my farm in Virginia where [he] remained until 3 October, 1937, when he was returned to the laboratory in Baltimore.

On first arriving in the country he showed in a marked degree his antipathy toward people [who] had been associated with him in the experimental environment. To these he reacted [as he] had to a neutral stimulus such as a light which had concurred simultaneously with the [tone]. Thus when I met him at the station and led him up the road, instead of running to me as most dogs who have been separated from people they know are accustomed to do, he [paid] absolutely no attention to my calling him and to other friendly gestures, but gave even a negative reaction, turning his head in the opposite direction and strongly attempting to pull away. Towards strangers he was much more friendly, a characteristic of his even to 1943. After several days in the country he became less negative toward me, barking and jumping up on me when I approached. Most of the time while there he was kept on a forty foot chain. Jealousy of other dogs seemed to bring out the anxiety state; thus when another dog was brought into the "family" on 7 August Nick became much more agitated, running and barking furiously, showing behavior noted by several people as extraordinary.

Toward the food that he had received during the experiments in Baltimore (Spratts ovals) he reacted for the first few days in the same way as he did in the experimental camera, picking them up and dropping them. Afterwards he ate them readily, though in 1939 they produced the anxiety-like state again, as will be described later.

Toward a new dog he acted aggressively as he had done in the laboratory, bristling his [hair], without however coming to the point of fighting.

He did not know how to swim when first brought to the farm, though he learned soon after being put into the water. On three occasions he had disagreeable experiences—once when thrown into the water, the second time when he became entangled in his chain which [held] him tightly where I had left him tied, and on a third time when leashed to the back

of my bicycle his foot got in the chain and he was dragged for some distance [illegible] these he appeared less friendly toward me for several days, showing the [illegible] seen in the laboratory. When taken for a walk after these experiences there [illegible] and pollakiuria (every two or three minutes, though only a few drops) [illegible] vigorous scratching with all 4 feet, growling, and penile erections. The effects [illegible] experiences and the laboratory environment were very similar, though the latter [illegible] and was much more severe.

On 3 October, 1937, he was returned, having trotted 6 miles and walked [illegible] station behind my bicycle. During this journey he became quite excited, [illegible] not go further without rest as his foot was bleeding from a stone cut. Apparently [illegible] ill effect from this exhausting journey. This is in keeping with my [illegible] experiences *per se* are much less powerful as a cause of disturbed behavior [illegible] disturbance or "conflict," and indeed they may leave no trace of their effect [illegible] system as measured in the crs, while a conflict of only a few seconds' duration [illegible] effect for days.

He was left overnight with strangers, and shipped the next day by train [illegible] spite of this fatiguing episode and being in strange quarters, his behavior [illegible] showed a marked improvement. Whether this was a result of the beneficial [illegible] rest, or whether because he did not associate his fatigue with me, as he had [illegible] ated other disagreeable incidents in which I was more intimately involved, [illegible] determined.

When returned to the laboratory on 5 October, 1937, he ran willingly [illegible] and jumped on the stand. He ate outside but not inside the camera. [illegible] the tone had little effect on him, neither upon his eating nor did it make [illegible] previously had.

There was no urination in the experimental room, though there was a [illegible] A specific defense cr was present, as had been previously and regularly seen [illegible] H.S., "All right Harry, turn on the tone." The cr movements consisted in slight [illegible] and whining but not so much as formerly. On this day there was definitely less [illegible] less fawning, and none of the peculiar raucous breathing (except very briefly [illegible] he was last in the laboratory.

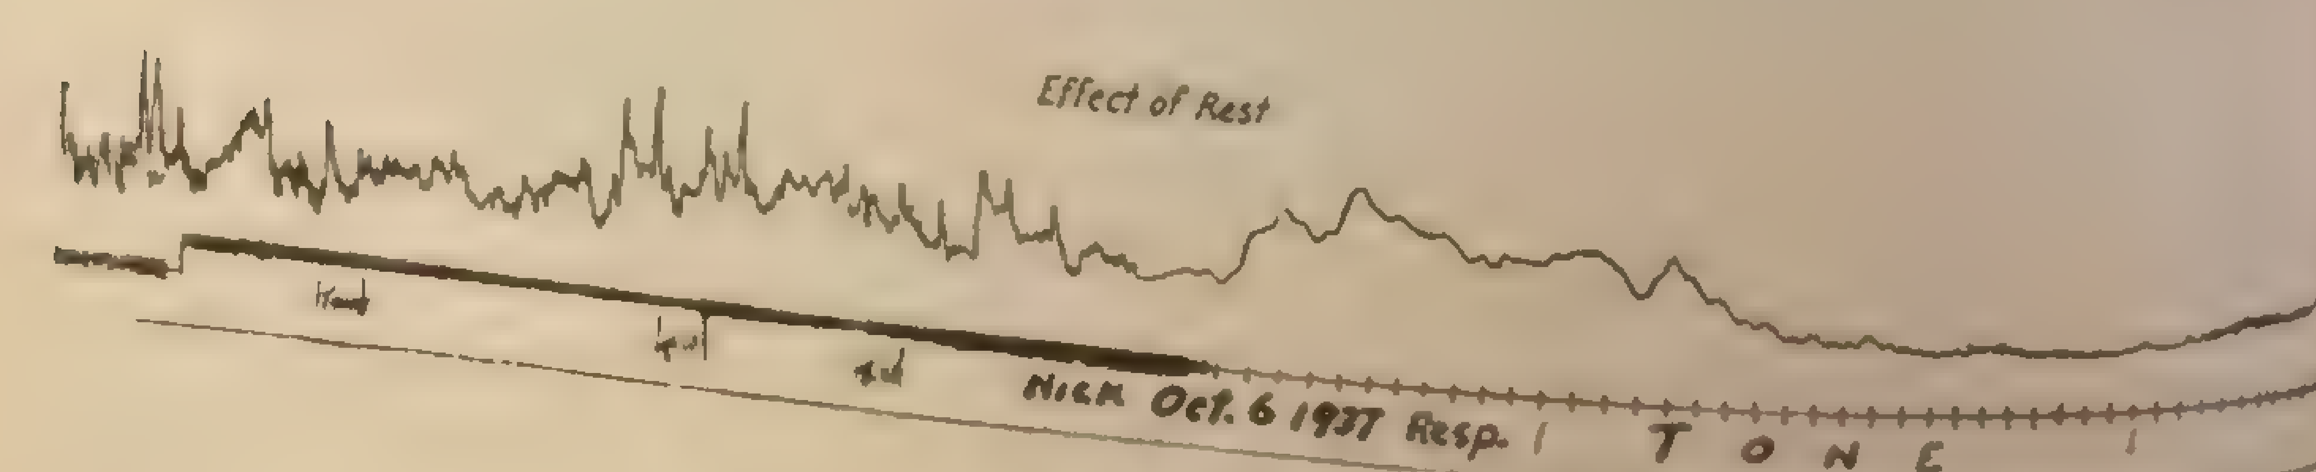

FIG. 10.

His behavior continued to be much more normal during the next month. [illegible] 6, 8, 13, 14, 19 October and until 11 November he was relatively quiet in the [illegible] room and camera—to the tone there was only slight whining, a brief [illegible] and less retreating. An examination of his respiratory record shows that the [illegible]

[illegible] effect upon his breathing movements on 8 October, 1937 (fig. 10). All these [illegible] Nick [illegible] from his overt behavior that he was markedly improved. The fact that this improvement lasted over a month suggests that it was due to the rest rather than to the shock [illegible] during his running to the station.

On 14 October, 1937, in the experimental room he was somewhat more restless than he had been on the 5th and 6th. During the tone he looked anxiously to the door toward the [illegible] of the tone, retreated twice to the camera and had a slight sexual erection (fig. 11).

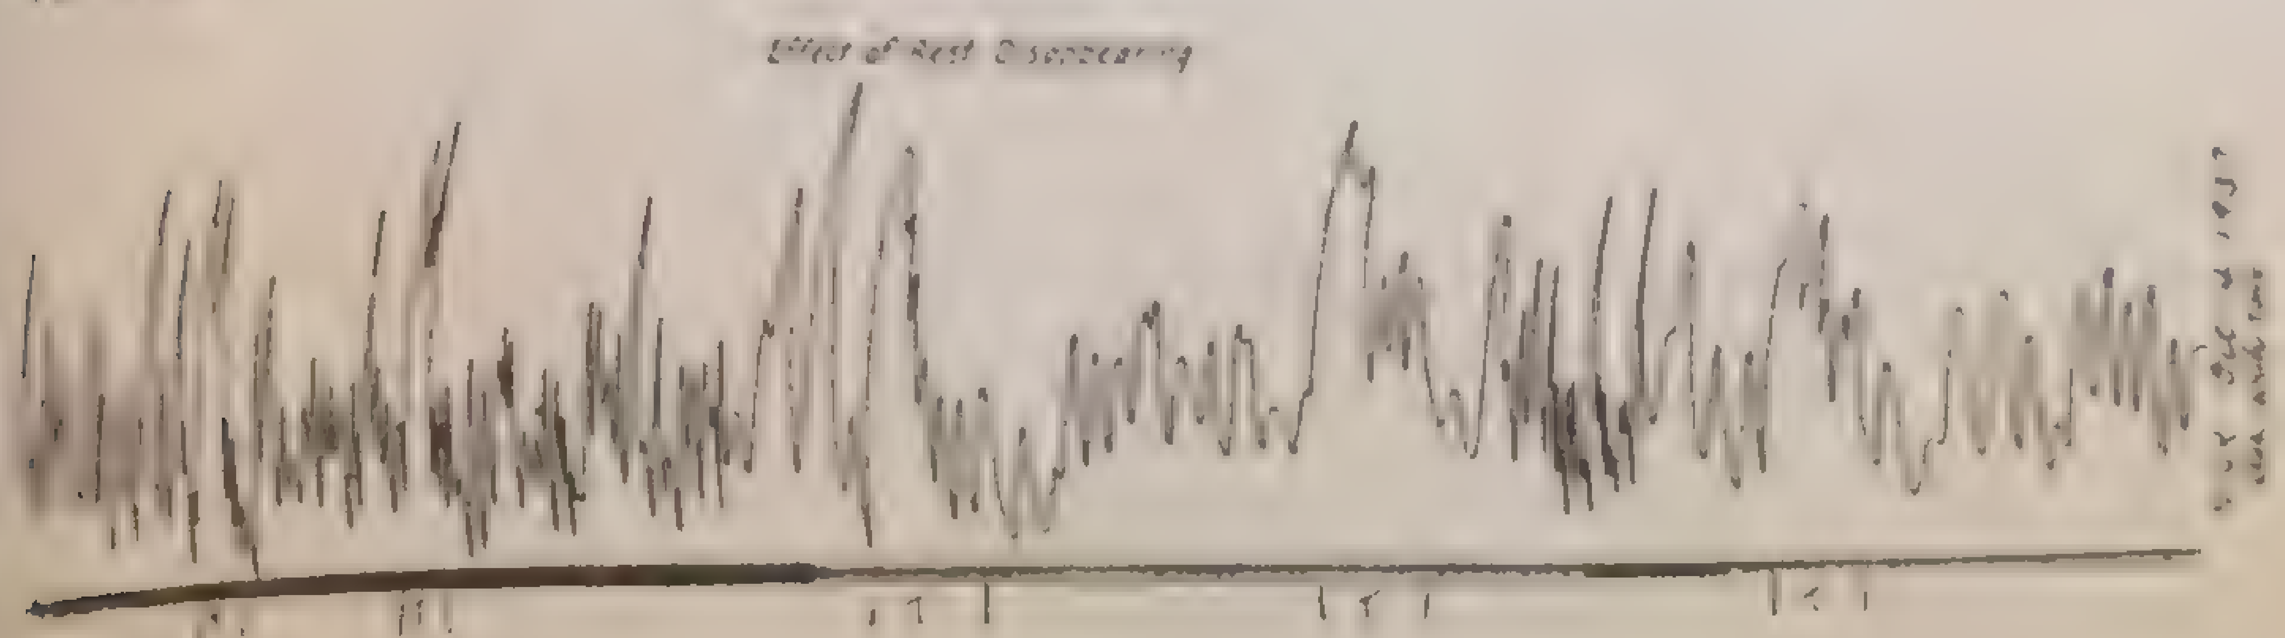

FIG. 11.

On 11 November in the paddock Nick was quiet and ate the ovals. When brought into the experimental room he showed the same violent, raucous breathing, was very restless, and would not eat. He dashed in and out of the camera. There was a marked state of anxiety to the tone with increased respiratory rate. Sexual erections began when he was taken into the camera and increased during the time of the tone, lasting altogether 10 minutes.

## 1938

The effect of the tone was tried on 3 January, 1938, and again on 12 January. On the latter day the ovals held in front of the snout showed that there was inhibition of the natural food reflex to the sight and smell of the food, as no saliva flowed from the salivary fistula, though there were a few drops when the crackers were forced into the mouth. This is evidence of the deep inhibition caused by the environment. Not only were the artificial food CRs inhibited, but also those older and stronger ones dating from early puppyhood associated with the sight and smell of the food. However the salivary UR was not abolished (Table 24). The second time on this day that the tone was given there was much more marked reaction than there was for the first time—retreating, whining, sexual erection.

On this day experiments were done to show the effect of the *social factor* on the anxiety. Although it had been previously noted that the approach of a person who had worked with the dog would often bring on the raucous breathing and other pathological symptoms, contrarily we saw that standing close to the animal and more particularly stroking and petting him prevented or dissipated the symptom of anxiety. Thus when I or either of two strangers (H.S., K.) petted the animal there was no reaction to the tone, but the tone tried alone on the same day gave the typical reactions—whining, dyspnea, retreating, erection (fig. 12).

On 14 January, 1938, Nick would not eat in the experimental room nor in the camera.

An [illegible] bulldog (Billy) was present with him, which probably [illegible] [illegible] while on the stand. That the dissipation of the defense reactions did [illegible] from the diversion of an extraneous stimulus (external inhibition) was [illegible] [illegible] effect of the dog Billy and that of the human being; the anxiety was [illegible] my petting the animal (fig. 12) but was not changed by the presence of [illegible] [illegible] in there with him. See the respiration record for 14 January (fig. 13).

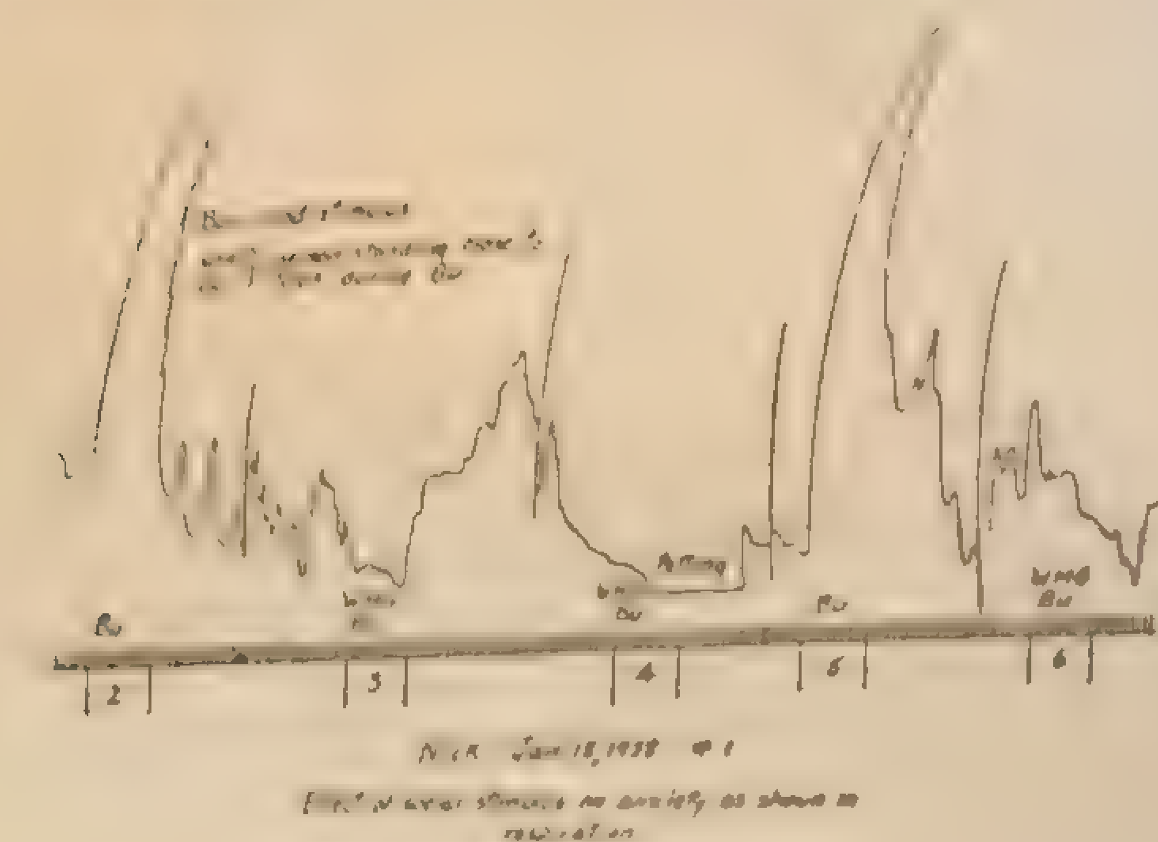

FIG. 12.

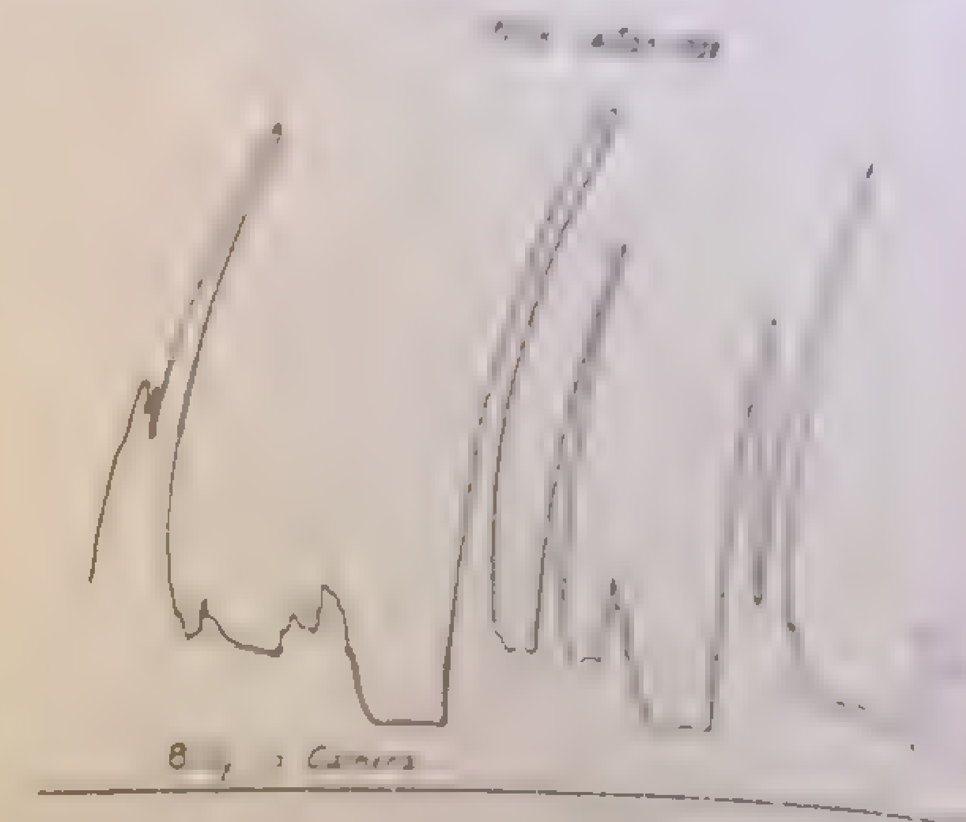

FIG. 13. Lack of effect of [illegible] flict in Nick: compare effect of [illegible] 11 and 33).

On 17 January the effect of petting the animal—rubbing him behind his ears beg[illegible] seconds before the tone—quieted the animal so that there was absolutely n[illegible] tone, i.e., no disturbed breathing or movement until he left the camera, nor [illegible] erections while the dog was in the camera. When the ovals were held under t[illegible] for one minute he refused them, turning his head away, and started panting.

On 18 January he would not eat outside of the camera in the experiment[illegible] dashed rapidly in and out. It was seen that other auditory stimuli such as M60, [illegible] through water, gave the identical anxiety-like reactions as did the tone of 1000 [illegible] the presence of W.H.G. or H.S. in the camera with the animal markedly [illegible] defense reactions; they were also more intense when the door was closed and [illegible] alone (figs. 12, 33 and 44).

On 19 January I demonstrated the effect of another dog, Lucy, put into the camer[illegible] Nick. An examination of the record shows that, in contrast to the presence of a [illegible] this other dog had no quieting effect upon him. Lucy was the same dog which w[illegible] some months previously had a markedly calming influence upon Nick but [illegible] lutely no effect—comparable to the neutral effect of a male dog Billy placed in [illegible] with Nick on 14 January (see respiration record for that day, fig. 13).

The effect of the light associated with the auditory stimulus, as noted before, [illegible] an anxiety-like reaction beginning about 3 seconds after the light was turned [illegible] onds before the tone. (The light was given 5 seconds before the tone and then 5 sec[illegible] gether with the tone.)

On 7 April when the salivary disc was applied—the first time for several months—[illegible] jerked his head away, tucked his tail and went into marked tremors, especially of the legs. The disc represented an added stimulus from the previous experiment of conflict [illegible]

[illegible] outside the camera, at first he would not eat Spratts ovals although he took them after a few minutes.

On this day, at the beginning of the experimentation Nick showed the same retention of the conditioned anxiety-like movements to the light, and the anxiety became intensified to each repetition of the light.

On 13 April, when there were visitors and two other dogs in the room, Nick was slightly aggressive toward the dogs, sniffing at them and bristling up, growling but not fighting. He urinated 3 times in the experimental room during the first few moments; he showed exaggerated activity, dashing in and out. In the first 10 minutes that he was in the camera there were definite spontaneous erections lasting a few minutes each and associated particularly with the csi.

From 17 May, 1938, artificial sexual reflexes were measured and for the following year experiments were conducted to study the effect of alcohol on the sexual reflexes. These results are summarized in another place (*40*) (fig. 48); here I shall note only marked deviations in his behavior.

When 32 cc. of 95% alcohol (2 cc./kgm) were given in a 20% solution on 17 May, Nick became ataxic, falling over backward when he attempted to sit. His behavior was moderately slowed by being "drunk" in the camera; he ate readily from the hand and even took food from the shelf and food box while he was on the stand, which he had rarely ever done, but he did not eat after being put on the leash. For an hour and 15 minutes after the alcohol he would not eat either inside or outside the camera. The alcohol either increased the food excitability or diminished the anxiety state, but it did not remove the anxiety to the tone itself. Also the same quieting effect of petting the animal during the metronome was seen as it was on control days. On 19 May Nick was much calmer than usual; he ate from the floor of the camera until he was put on the leash—possibly the effect of the alcohol two days before. Also on the 23d Nick was markedly quiet, giving only a slight reaction to M60 and other auditory csi without whining or barking. Sexual excitability moreover seemed to be increased on this day, for the induced erection was extreme and lasted 14½ minutes—much longer than ordinarily. On the 25th the behavior was similar with an erection lasting 13½ minutes; on the 27th lasting 16½ minutes. On 30 May were observed spontaneous erections, raucous breathing and some anxiety-like reactions.

During June and July Nick was brought down about 3 times a week for the study of induced sexual erections and alcohol. The duration of these erections was 3 and 4 times longer than they had ever been before, i.e., from 10 to 18 minutes. The next dose of alcohol was given on 20 June. As Nick would not drink the 20% alcohol it had to be given by stomach tube. Similar to what happened with the first dose of alcohol, he ate in the camera and from the food box, and jumped up on the stand readily, looking for food. There was also no anxiety-like reaction to the tone, and on this day the alcohol seemed to abolish completely the defense reactions to the tone.

Sometimes in Nick a sexual cr (erection) was noted when he first entered the camera and jumped upon the table. This was apparently conditioned to the procedure of inducing the erections rather than a component of the anxiety state. In some other dogs used as control it was, however, impossible to form sexual crs to the procedure that we used.

It is highly significant that the sexual reflex conditioned to our procedure of [illegible]
excitation was much shorter in duration and *less intense than the sexual re[illegible]*
*part of the emotional state* of the "neurosis."

Sometimes Nick could be coaxed to drink alcohol diluted to 25% with milk, [illegible]
ally refused it.

One cc. kgm of alcohol gave no visible effect on his behavior. The effect [illegible]
reflexes are noted separately in Ch. VI, section 6.

From 22 July, 1938, until 21 October, 1938, there was no experiment [illegible]
October 3 months after his last dose of alcohol, he again became agitated. T[illegible]
same raucous breathing, and although he ate in the antecamera he would not [illegible]
camera even before the leash was attached. To the metronome, tone, bell, and [illegible]
were defense reactions, but these were very slight. Nick was, in general, a little [illegible]
usual. The same fetid odor was noted, however, with Nick in the camera as [illegible]
when he was particularly disturbed.

On 2 December, 1938, Nick ate both outside and inside the camera until the [illegible]
given; after this there was an erection, refusal to eat, raucous breathing, etc. La[illegible]
the experiment an erection occurred to an extraneous auditory stimulus (click of [illegible]
Also to the light there were defense reactions with sexual erection lasting 30 sec[illegible]
on the 8th trial of the tone, sexual erections and defense reactions were noted.

On 30 December when Nick was brought down he was hyperactive as usual [illegible]
ate the crackers even inside the camera on the stand. The tone elicited a sexual erect[illegible]
defense reactions; these appeared to every auditory cs and in a slighter degree t[illegible]
Even when a collaborator (Löwenbach) whistled while the dog was eating the f[illegible]
experimental room, he dropped the food out of his mouth during the whistling; th[illegible]
mechanically each of 5 times that it was tried. The defense reactions to the tone [illegible]
sipated by the petting of a visitor (M.R.) as well as that of W.H.G.

*1939*

On 11 January, 1939, Nick showed increased anxiety and raucous breathing [illegible]
brought down toward the experimental room, although when observed immediatel[illegible]
in the paddock, he was quiet. Inside the camera he ate until the leash was attached. [illegible]
it was the *leash plus the environment* which stops the eating was shown by his eating [illegible]
on the leash outside of the camera *if* he was fed from the hand of strangers (Drs. A[illegible]
Leighton, Rich) neither of whom he had seen before, but he refused to eat from [illegible]
or that of J.S., the brother of H.S. who ordinarily worked with him (J.S. is a techn[illegible]
another floor in the Medical School).[20]

In addition Nick would not eat from the hand of a collaborator (H.S.). This be[illegible]
parallel to his running to visitors in the laboratory in preference to those who work [illegible]
him, and his marked avoidance of me when first taken to the country in 1937. Such b[illegible]
in Nick was demonstrable repeatedly.

On 13 January, 1939, Nick showed the same stereotyped anxiety and defense [illegible]

[20] This is probably family association, for I noted that Nick reacted similarly to member[illegible]
family while in Virginia. It may be based on olfactory family resemblances.

[illegible] by the presence of several strangers and the apparatus and lights used in making [illegible].

When brought on the morning of 29 March, he urinated in the anteroom [illegible]. His heart rate was accelerated, showing the effect of the presence of someone with him; it varied from 128, while I was standing by him in the camera, to [illegible] immediately after the [illegible] were elicited by the old food cs.

During April, May and June, experiments designed to elaborate a sexual cr as well as [illegible] of the study of the effect of alcohol were performed.

On 19 April the increase in heart rate on entering the camera was about equal to that following the tone; the rate quickly returned to normal when the tone stopped. There was only a slight increase in heart rate to the bell (a cs for the sexual reflex) and also only a slight increase during ejaculation—these increases are much less than those accompanying the anxiety state.

On 6 May the behavior of Nick was contrasted during a demonstration with that of a normal dog ("Billy") who had also worked about the same length of time in the experimental camera. "In their paddocks at 10:20 both are lying down quietly. Nick immediately gives the loud raucous breathing when taken out of the paddock, he runs first to the [illegible], while Billy runs first to me; Billy takes meat from my hand, while Nick runs around in circles panting. When brought down on the elevator this raucous breathing continues. When the tone was tried at 10:26 for 30 seconds, Billy gives it no attention and continues to eat, while Nick drops the biscuit from his mouth, urinating during the tone and [illegible] the next two minutes; 5 minutes after the tone he begins eating again. At 10:31 Billy runs in and jumps on the table in the camera while Nick dashes in and out [illegible]. At 10:33 when Nick is on the leash he refuses food. At 10:34 while the tone is given with Nick in the camera, there are marked defense reactions—backing away from the [illegible] of the tone, appearance of erection in 10 seconds after the beginning of the tone (the erection lasts for 4 minutes, the penis being protruded about 9 cm.), rapid panting." None of these symptoms were seen in Billy.

On 11 May when Billy and Nick were brought into the experimental room together for a demonstration practically the same behavior occurred as on the 6th. On this day it was noted that Nick gave not only the spontaneous erection to the tone but both the spontaneous erection and the typical defense reactions to a verbal signal—when I told the laboratory [illegible], as I had done frequently, "Go ahead Harry give the tone." On this day the erection to the tone for 10 seconds lasted about 2 minutes. Both the erection and the defense reactions disappeared when either I or a stranger (W.H.) were standing by and petting the dog. One minute later when the tone was given in the absence of a human companion, Nick gave the typical reactions—defense movements and spontaneous erection—although another dog, Billy, was in the camera only 2 feet from Nick's head. It is thus evident that the human companion, when he is petting Nick, has a specific relationship in dissipating the anxiety. The human, contrariwise, is a factor in the initiation of the anxiety. The effect of a female dog in estrus had a similar quieting, though more prolonged, influence on Nick, while the same female out of estrus or a male dog was entirely without effect upon Nick.

On 26 May it was noted again that the bell which had been used as a cs for the induced

sexual reflexes for some months every other day or less frequently, [illegible] 30 seconds after the beginning of the bell. This erection was slight, [illegible] 15 seconds), in strong contrast to the erections (lasting for several minutes) [illegible] component of the anxiety state. On 26 May Billy and Nick were again [illegible] camera with the same results as noted above, viz., Billy eating [illegible] tions and Nick stopping immediately when the tone was given even though he [illegible] free in the antecamera. During the first 5 minutes that Nick was brought d[illegible] 3 times on the leg of the table in the camera; Billy never urinated in the cam[illegible] Nick was seen lying quietly in the paddock until som[illegible]

On 3 June again, Nick was seen lying quietly in the paddock until som[illegible] him when he began the peculiar type of respiration. His preference for str[illegible] demonstrated by his running to Dr. Ischlondsky, a visitor, instead of to those wh[illegible] with him. He urinated 6 times in the camera on the table leg. There was a very [illegible] when the door of the camera was left open but a marked erection with the door [illegible] from his human companions).

On 8 June Nick urinated twice the first minute he was in the antecamera. Whil[illegible] dog was in the camera and Nick was running free outside, some distance from [illegible] there was evoked by the tone a marked erection with protrusion of the penis for about [illegible] however, 7 minutes later absolutely no cr erection to the bell occurred, again demo[illegible] the predominance of the sexual erection accompanying the psychopathological stat[illegible] which was conditioned directly in the ordinary manner of forming artificial crs. On [illegible] when brought down for demonstration, Nick urinated 5 times in the first 4 minut[illegible] the experimental room, stopped eating to the tone, ran and jumped on Dr. Kluev[illegible] in preference to either the assistant H.S. or W.H.G.; there was an erection beginni[illegible] onds after the onset of the tone and lasting for 100 seconds. He refused food [illegible] camera.

On 25 August, 1939, Nick was transported by train to the farm in Virginia. At [illegible] that morning in the antecamera his heart rate was 205. In the baggage room at the st[illegible] he urinated 15 times during the 10 minute wait.

In Virginia on 28 August at 11:50 a.m. his heart rate was 110, and 5 minutes later [illegible] He was very active and panted slightly. On 27 and 28 August Nick showed great [illegible] ment toward a female in estrus—scratching the earth vigorously, kicking out his [illegible] ing frequently on the ground where she had been lying. On 29 August his heart rat[illegible] from 110 to 150. Although the dog appeared quiet externally when I approached, ther[illegible] an increase in heart rate without external changes in the behavior.

On 11 September the heart rate varied from 97 to 113. It was seen at this time that [illegible] learning capacity was acute, e.g., after twice striking against an electric fence wire he [illegible] not touch it again; when pulled that way, he nimbly hurdled it.

On 12 September the heart rate varied from 105 to 118 in the presence of hum[illegible] reached 130 when a male bulldog growled aggressively and approached him to w[illegible] foot (they were held apart on leashes). Nick also growled somewhat. The second tim[illegible] this bulldog was brought within 6 inches of Nick, the heart rate did not exceed 118.

On 28 September Nick's heart rate in the presence of human beings varied from [illegible] With a cat clawing his back it was only 100, while with the aggressive bulldog allowed [illegible]

[illegible] his heart rate was 140 while he was breathing, though only 100 when they were [illegible] them together [illegible].

It is thus clear that the real danger, that of an aggressive bulldog, or the actual pain of being chased by a cat, produced less excitement, judging both by external appearance and by the heart rate, than the laboratory situation involving "anxiety."

On 3 October, when taken off his leash and allowed to run, he became very excited, panting [illegible] at times. It was observed on this day and on some other occasions that Nick ran to some person when he defecated, [illegible] around rapidly and pressing on his [illegible] and marked erection (protrusion of the penis for about 10 cm.) lasting for two minutes.

On 14 December there was the typical noisy breathing when W.H.G. approached. Given [illegible] snacks—the same kind of food he had during the experiments in the laboratory—he took them in his mouth but dropped them without chewing, then became excited, running around in circles. When I dropped the biscuits in his food basket he ran up to them, [illegible] them, then immediately urinated on them 3 times within one minute. This urinating in the vessel from which he usually ate and upon food is an unknown act for a normal dog. [illegible] will be discussed later. On 20 December at 9:38 a.m. his heart rate standing [illegible] was 140–150; 150–160 when offered the [illegible] snacks and graham crackers. Nick was very restless on this day, turning on his back and struggling when the electrodes were attached. He urinated 3 times in the room when his heart rate was measured.

*1940*

During 1940 Nick was kept on leash most of the time on the farm, though during [illegible] he was allowed to run at will. He was cared for by a farm hand with whom he was [illegible] friendly. In July and August I was with Nick on the farm and fed him. He attempted to follow me everywhere. He was returned to the laboratory 14 January, 1941.

On 23 February, 1940, on a visit to Nick at 12:15 when he saw me coming he crouched, then lay on his back. An erection occurred when I was at a distance of about [illegible] feet; it lasted for 2 minutes with ejaculation for about 10 seconds. The heart rate during ejaculation was 1[illegible]; 1 minute after, 80-120 (both times lying on his back). At 12:17 his heart rate was 7[illegible], still lying on his back. There was no urination during this morning observation. At 12:18 a measurement of the sexual reflexes was about the same as it had been in the laboratory (see fig. 43 and Table 27). At 15:30 Nick was quiet, there was no panting, the heart rate was 75. At 16:30 he was seen to urinate twice in his pail of water, an action which the attendant says he did frequently, but as pointed out, an unusual act for a normal dog.

On 14 March the heart rate was 90, Nick lying on his back. When I was near him there was a slight erection without ejaculation, lasting 60 seconds. His attitude toward me and toward the attendant was noticeably different: he crouched when he saw me, then rolled over on his back, while he jumped up on the attendant in a friendly manner.

The same contrast in his behavior was again seen on 30 March. At 15:00 with another farm hand who never fed him but sometimes saw him he was very friendly, climbing up on him with his forelegs. At 15:01 when I approached or touched him there was a marked erection, and he crouched on the ground at my feet. Again at 16:00 when I came near he crouched and there was an erection which became more pronounced when I patted him on

his side; the erection lasted over 1 minute. At 16:05 when the attendant patted [illegible] same way as I did Nick instead of crouching, climbed up on him with his forefeet [illegible] was no erection.

On 31 March at 11:00 with the attendant there was no erection and Nick [illegible] on him with his forefeet as he did the day before. At 11:05 when I was standing [illegible] he sat at my feet then turned on his back. When I touched him on the side, [illegible] appeared within 2 seconds, lasting 30 seconds and accompanied by ejaculation [illegible] seconds.

On 5 May at 7:00 with the attendant patting him, Nick climbed up with his [illegible] there was no erection. At 7:02 when I stood near him he started to climb up [illegible] crouched and an erection began in about 5 seconds and lasted 1 minute. While I was [illegible] him he turned over on his side. At 14:00 his behavior was identically the same wit[illegible] had been in the morning. On this visit and on some others I observed that Nick [illegible] panted frequently; the attendant said he did not do this nearly so often as when I [illegible] there.

On 12 May I arrived on the farm but did not approach Nick closely till 13 May [illegible] Nick crouched when I went up and touched him, then started to jump on me, the[illegible] on his side, later on his back. There was a slight erection for a few seconds, with [illegible] of the penis for about 3 cm. and ejaculation for 10 seconds while he was on [illegible] 12:01 when I went up and touched him he vacillated between crawling up [illegible] turning on his back. At 12:05, when a member of my family (my four year old [illegible] up to Nick, there was also a slight erection, slight crouching and behavior intern[illegible] tween that toward me and toward the attendant. The only explanation that I [illegible] (as Nick had never been closely associated with my little boy before) was that [illegible] reason, perhaps olfactory, Nick associated him with me, as he had previously done [illegible] member of my family. At 12:10 Nick climbed up on the attendant in a friendly [illegible] there was no crouching and no erection, but immediately afterward Nick retreated [illegible] me a few steps.

On 20 May at 10:00, Nick panted loudly when I appeared, crouched, rolled on [illegible] got up then crouched again. He made a half attempt to climb up on me. An erectio[illegible] when I approached him and continued without ejaculation for 4 minutes with protr[illegible] the penis for about 3 cm.

Sexual erections frequently appear in dogs in the spring or when they are excited, [illegible] stereotyped manner in which it is seen in Nick and its appearance with specific people, [illegible] light of Nick's previous history, undoubtedly is of another type and of greater sig[illegible] than simply that of normal excitation or of normal sexual excitation. Erections are [illegible] general in young animals than those of Nick's age.

On 25 May when Nick heard me several hundred yards away he started barking [illegible] panting. An erection began when I was still 40 yards distant. As I went up to [illegible] crouched slightly, turned on his back; there was a slight erection for 3 minutes wit[illegible] tion. After subsidence of the erection Nick crawled up on me.

In a control young dog (King) whom I saw for the first time on 20 May the[illegible] a slight erection and crouching—evidently timidity or fear—but in this same dog wh[illegible]

[illegible] Nick and was later brought to the laboratory, I never at any other time [illegible], nor have erections appeared regularly in any of my normal dogs.

In August [illegible] Nick appeared to be sexually potent. He frequently mounted for a period [illegible] the large male dog (King) about nine months of age, and he copulated [illegible] with a female dog in estrus; the puppies born resembled Nick.

After daily association with me and being fed by me during the summer his attitude was gradually changed. There were never any erections when I went up to him, he climbed up [illegible] instead of crouching, and his heart rate was 90-100. He devotedly followed me about, although the usual panting was at times present. On 12 September his heart rate was 100-[illegible]. When he was allowed to run loose he was more restless and excitable than the other [illegible], becoming quickly aggressive with them—bristling the hairs on his back but not fighting. He liked to come into the dwelling house; there he would eat readily and even beg for food. When I whipped him for jumping on the table he grovelled at my feet, but there was [illegible] no erection for the 30 minutes he was in the house, and he urinated only 3 or 4 times during 2 hours while running with me over the farm. His friendly attitude was in [illegible] contrast to the negativism he exhibited toward me when he was first brought down [illegible] country, and also very different from his attitude at the beginning of the summer. [illegible] noteworthy were the absence of pollakiuria and sexual erections, but the hyper[illegible] and the slight raucous breathing remained.

On 13 September, after his morning feeding at 8:55 I brought him into the same room [illegible] me for 35 minutes. His heart rate while there was 90-110. He climbed up on me [illegible] but lay quietly the rest of the time. Panting was quite frequent but there were [illegible]. He attempted to urinate twice—at 9:15 and 9:28—but was easily checked [illegible]. On 16 September, after running loose for several weeks, he was seen fighting [illegible] year male pointer (King) and attempted copulation with a small 4 year male. [illegible] it was noted that he could keep up with me driving the automobile at the rate [illegible] miles per hour for a distance of three quarters of a mile. On 17 September he lay [illegible] my chair in the house, showing no restlessness, panting or urination. On 18 September he was seen to urinate twice on a visitor's (J.D.P.'s) luggage, but in contrast [illegible] behavior in the laboratory, he was easily checked by a remonstrance and he did not [illegible] elsewhere. He appeared sexually hyperactive and mounted on this day a female [illegible] poodle (not in estrus) belonging to the visitor on whose luggage he urinated. Nick [illegible] rather aggressive in these sexual overtures and he was attacked by the poodle. This suggests aggression toward the intrusion of the strangers after he had become attached to [illegible]; the action of the poodle was a natural female defense.

His devotion at this time was more marked than that of two of my other dogs on the farm; he would follow me nearly everywhere, jumping into the car or running after it. His behavior with other dogs was not quite normal—he would either be aggressive toward them [illegible] attempt to copulate, and was often seen fighting with other dogs. This can be compared with the behavior noted in 1933 when he remained aloof from other dogs in the paddock.

On 12 October at 7:30, when H.S. who formerly worked with him in the laboratory but [illegible] had not seen him for over a year went up to him, Nick was at first indifferent, then he [illegible] away, then crouched at his feet and turned on his back. When petted by H.S. he got

up and ran away a few yards and urinated once. However [illegible] some day Nick fought vigorously with a male hound 2 years old [illegible] laboratory behavior of bluffing, running away and never fighting.

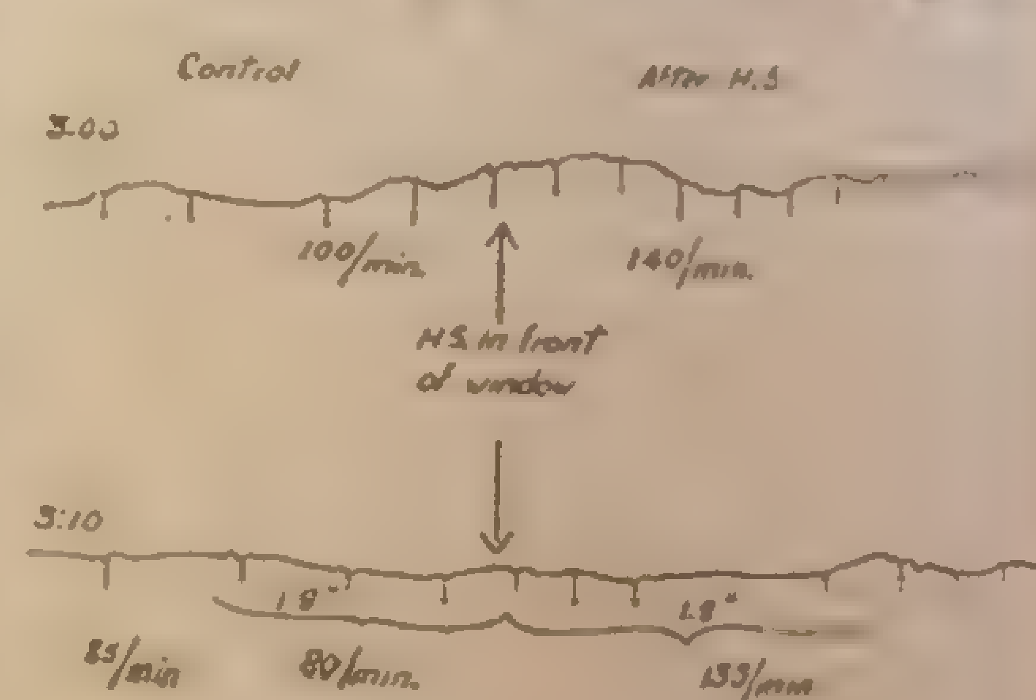
His heart rate varied from 115 when held by the farm attendant [illegible] me or by the laboratory assistant, H.S., whom I took to Virginia [illegible] on Nick. Nick had not seen H.S. for over a year. The cardiac acceleration to H.S. [illegible] not so great as it was in the laboratory. 30 minutes later at 12:05 when Nick [illegible] near a female in estrus his heart rate went from 125 to 150, and with a cat [illegible] spitting at him the heart rate was 140-150. In contrast to his earlier and [illegible] under greater stress, Nick was friendly and quiet with me; there was no [illegible] ing in my presence; his heart rate was about 80. On the 13th he lay quietly [illegible] the house without urinating for one hour; pulse 80-100.

The evidence for his improvement in the country was as unmistakable as [illegible] relationship to me.

*1941*

He was shipped by express to Baltimore on 14 January, 1941, arriving at 10:[illegible] day. Taken to the paddock by H.S., he pulled vigorously on the leash, running [illegible] corridor, not attempting to enter the laboratory (he formerly had halted at the d[illegible] to be taken in). He urinated at the door of the elevator, on the 6th floor corr[illegible] the paddock 7 times within 5 minutes, panting heavily. He paid little attention to H.S. [illegible] jumped up on a new laboratory assistant (A.E.) twice. During the day he [illegible] very friendly toward me. Thus the contrast to his behavior on the farm was [illegible]

On 16 January, 1941, his activity was still high but about one half of what it [illegible] he was in the laboratory before. When allowed to run loose at 14:00 he start[illegible] panting and jumped up on R.B., whom he had never seen, in preference to m[illegible] pletely ignored H.S. At 17:00, demonstrated before a group of students, there was n[illegible] raucous breathing, a pronounced erection (protrusion of the penis 2 cm.) for 9 [illegible] when he was first brought in, active running about and jumping on members of th[illegible] on R.B. His heart rate and respiration taken at 14:30 showed hyperactivity to the presence of H.S., even when he passed in front of the window (see heart records, Fig. 14).



*Effect of experimenter on heart rate (Nick) 16 January 1941*

FIG. 14.

When allowed to run in room 529[21] the raucous breathing appeared; he ran and jumped on A.E., then ran to H.S. but groveled at his feet, had a prominent erection lasting three minutes. He repeatedly (four times) ran to the feet of H.S., groveling and with erection, or else came near to H.S. when called but then crouched and turned away; on the contrary he jumped up on A.E. His behavior to A.E. and to H.S. is in striking contrast; to me it was intermediate.

[21] 529 is a large upstairs laboratory room where Nick had never worked before.

[illegible], now jumping up on me. Erection started while he was near H.S. and lasted while he was jumping on A.E.

Nick was quiet in the paddock most of the time after his return. When allowed to run in [illegible] raucous breathing began, he urinated but once in 529. He ran to A.E. and jumped on him, ignored H.S. completely though H.S. was standing by us and calling him.

When Nick ran into the new camera and slipped on the linoleum, he had a prominent erection immediately but it lasted only a few seconds—shorter than with the "anxiety" states. This was evidence that erection in Nick can be a reaction of fear as well as a component of the "anxiety" seen previously.

When allowed to run in 529 for 5 minutes (18:00-18:05), there was no erection but he urinated four times. He ran into the new camera when I went in, slipped down on the linoleum as he did formerly, had an erection with orgasm and ejaculation for 80 seconds, which quickly subsided when he went out of the camera. While in the camera Nick crouched at my feet after slipping down—another evidence that the erection is a component of fear. At 18:10 he followed me around, groveled at my feet having an erection at first, but after I petted him, the erection subsided and he no longer crouched and groveled but turned up on his back for me to pet him. When I told him to go away, he immediately had an erection for 10 seconds, with raucous breathing. He licked my hand, ran out eagerly with me when I got up to leave.

On 6 February, when running in 529, Nick was very playful with me, the same as he had been on the farm. This behavior is in contrast to the absence of playfulness before he was taken to the country.

On 7 February, Nick attempted copulation with a female who did not seem in estrus, after a few trials he finally inserted his penis for several minutes.

On 11 February, "while I am sitting in a room about 100 feet away from Nick's cage, he whines. Later when I release him he runs about the large room (529), sniffing where the female dog (D) who was in estrus had been, and urinating in certain places on the floor where he sniffs—apparently where she had left olfactory traces. After urinating he paws and scratches vigorously with all four legs, having a sexual erection as he had done in the country. The whole behavior is evidence of intense sexual excitation."

On 12 February, "Nick is whining in his cage when I approach. When released, he dashes out excitedly with the typical marked raucous panting. An erection appears as soon as he runs into my office, and also while he is running about in the large room between this and his cage."

On 20 February, "Nick has been much more restless in his paddock recently, with whining, barking, and jumping about in the cage. This is perhaps a result of a female in estrus (Omsk). He became very excited whenever she was brought near his paddock, though for the past three days she had not been close to him."

On 25 February, at 15:35, Nick was taken out of his paddock into the room where the female (Omsk) was tied. He immediately ran up to the female, began copulating without any preliminaries, and continued copulatory movements for 75 seconds after mounting the female. The duration of erection and union—from the beginning until withdrawal—was 23 minutes. To demonstrate in Nick the predominance of the sexual excitation over food

excitation he was offered dog biscuit (Kibble), which he ordinarily [illegible] times he refused although Omsk, the female with whom he was copulating [illegible] pate this inhibition of the food excitation by sexual excitation with the inhibition [illegible] movements by the sexual activity in Nick as seen previously).

Nick was returned to his cage until 18:02; on being released, he ran [illegible] Omsk had urinated, several times over places where she stopped. At this time [illegible] however, comparatively quiet; he did not show the customary restless d[illegible] haps a relief of tension after coitus.

On 27 February, Nick was taken into a new camera at 15:50 and his h[illegible] This was somewhat elevated over what it had been on 16 January when he w[illegible] back from the country, 120 now compared to about 100 then. His respirati[illegible] rapid—150 to 200 for 5 minutes.

At 16:10 Nick was taken down to room 120—the experimental environm[illegible] flict—where he had not been since 25 August, 1939, when his heart rate [illegible] effect of the prolonged absence from this environment, possibly plus an influ[illegible] in estrus on 25 February, was clearly evident in the much less agitated general [illegible] the nearer normal heart rate. However, that the environment was still potent as a [illegible] stimulus could be seen from the refusal of food, the slight retreating movements [illegible] auditory stimuli in the camera, the inhibition of the food secretory crs, and the [illegible] effect on sexual reflexes in normal coitus. A detailed description of the experim[illegible]

Nick ran around fairly actively but he was much quieter than before going [illegible] in 1939. He did not dash in and out of the camera, nor violently jump on and [illegible] as he used to do. He still preferred strangers, jumping up on the doctors and stud[illegible] at this demonstration but never once approaching H.S. or W.H.G. He ate the ovals [illegible] and outside of the camera and even on the stand. The fastening of the leash w[illegible] to inhibit the eating. When the salivary disc and electrodes were attached h[illegible] from the food and gave practically no secretion even when the biscuits wer[illegible] his nose—inhibition of a strong natural cr. With the food forcefully put into his [illegible] however, there was a small secretion (UR), though there was none to the met[illegible] bubbling sounds; to these he backs off from the corner whence the tone used to [illegible] which location was changed 6 years ago. The reactions to the auditory stimuli were [illegible] passive defense—retreating—without any element of the normal investigatory reflex. [illegible] ever the whining, barking, and extreme violent movements formerly present [illegible] this defense.

He was much quieter when someone (E.B.A.) was in the camera with him; [illegible] had been demonstrated throughout his life.

About 16:40 the female in estrus with whom Nick copulated on the 25th was [illegible] down. When this dog was tied on the floor in the camera about 3 feet from Nick his [illegible] to the disturbing auditory stimuli changed only slightly. Not until she jumped on [illegible] and sniffed at Nick did he pay attention to her, and then his anxiety-like respons[illegible] metronome was almost abolished. When taken off the leash he mounted her and [illegible] copulate with her several times on the table but ineffectually; also inside the cam[illegible] floor after several mountings, coitus was not completed. When taken outside the cam[illegible]

... room he had to mount her and get down 5 times before effective union ... was incomplete), in spite of the fact that the female appeared in a most ..., sniffing and rubbing up against him. On the 5th trial orgasm occurred ... after beginning of coitus and union lasted for 19 minutes compared with 23 min... days before. The environment of the antecamera (conflict) thus had a markedly ... effect on the latent period of erection, less on its duration. The chief difference was ... the duration of the erection but in the long preliminaries. The single comparison would ... significant except for the many other similar observations previously made.

During this union and for some minutes after there was, as previously noted, a refractory ... some minutes when the metronome had no effect on Nick. For the first 15 minutes ..., the metronome had no disturbing effect on Nick (shown by the absence of usual ... reactions), but when the metronome was given again at 19 minutes Nick imme... withdrew and dismounted.

"After coitus Nick eats readily both in the antecamera and in the camera, and there is ... no defense to the metronome for several minutes after coitus. In marked contrast to ... fumbling with food, he does not even drop it though the metronome is sounding. ... non-reactivity to the metronome is another instance of the refractory period following ... excitation."

On 19 January in room 529, Nick's heart rate averaged 99 between 14:31-14:48, con... electrocardiograph. On 27 February (six weeks after his return to the laboratory) ... old experimental environment (room 120), the heart rate while Nick was standing ... in the camera was 123; during the action of the metronome it went up to 134.

Summarizing the effect of the 17 month removal from the experimental environment of ..., Nick showed less general hyperactivity in his running and jumping, no whining nor ... to the metronome; but he retained the reactions to stimuli of the past rather than ... of the present, revealed in the inhibited salivary and food crs and retardation of the ... reflexes.

On 28 February, 1941: Nick was quiet in his paddock. When brought out and allowed to ... in room 529 there was a moderate sexual erection, moderate pollakiuria (6 times in 5 minutes); when placed on the stand in the camera he urinated on one of the supports even ...h he was on leash. This is the only instance that I have ever seen either here or in Pavlov's laboratory of a dog's urinating on the stand, although some of them are kept there 7 or 8 hours during prolonged experimentation. The urination may have been caused by the scent of the female in estrus, although other male dogs brought in on the same day did not urinate there. There was some panting and noisy breathing while Nick was running around.

On 22 March Nick was transferred from an inside to an outdoor cage. He ran quickly up the steps, but as soon as he entered the paddock (one which he had occupied before going to the country) he defecated and urinated immediately, having a marked erection, but lasting only a short time—about 3 seconds during the defecation.

During March 1941 a study of the effect of the experimental environment on sexual reflexes was carried out by measuring on alternate days sexual reflexes when Nick was inside the camera and when he was in the antecamera. Contrary to previous observations before he

had been taken to the country, there was no appreciable difference between the [illegible] flexes in these two rooms. There was, as has been noted previously, a wide fluctuation [illegible] duration of erection, from two minutes to twelve and one half minutes. See chart [illegible] reflexes under discussion of special symptoms.

On 14 October, "Nick had been in his paddock in the medical school since [illegible] brought down today for demonstration, he exhibited the usual behavior—[illegible] respiration, running to the feet of a stranger (D. J. Larson) in preference to W.H.G., H.S., dashing in and out of camera, jumping on and off the stand, refusing food. [illegible] he was fastened on the stand there was immediately a slight erection, with protru[illegible] about 1 cm. lasting 3 minutes."

*1942*

On 13 January, "Nick brought down to 529 by H.S., at 16:30. Fairly quiet when [illegible] when released runs about panting. Will not go to H.S. when called, though climb[illegible] student whom he has not seen before, on A.E., and on W.H.G. Goes into camer[illegible] floor (probably where female has been) and has sexual erection for 2 or 3 minutes. N[illegible] ing in and out of this camera. Begs for food by standing on hind legs and eats gr[illegible] pan of biscuit moistened in cod liver oil."

"At 16:45 taken to room 120. Dashes in and out of camera, jumps on and off tabl[illegible] increased panting and agitation. Eats from same pan as he did in 529 both inside and [illegible] camera. Continues eating during first 20 seconds of Bu, though afterwards hesitates. A[illegible] third repetition of Bu, Nick will no longer accept the same food that he ate greedily [illegible] but turns away from it; he gives slow labored respiration during Bu, and backs off [illegible] former position of tone. When released at 16:55 he eats in the camera again. In the [illegible] camera he eats greedily, but stops, walks away and whines when A.E. whistles. This act is repeated to the whistling for three times at about 1 minute interval, during which [illegible] turns to the food. On fasting stomach, there is hyperacidity." (See next chapter.)

On 20 January, "In 529 Nick brought down for taking gastric juice with tube. S[illegible] as usual without aggression. In the presence of two strangers (Drs. Rich and Whitel[illegible] runs and jumps up on them but by-passes H.S., will not go to him even when he calls. [illegible] When J.C.W. transfers Nick from himself to H.S., Nick immediately crawls down [illegible] tail tucked. Hyperacidity found in the fasting stomach."

On 19 March, in order to determine the therapeutic effect of replacing the conflict [illegible] training using the same csi but basing them upon another UR center (Pavlov's terminolog[illegible] or drive (psychiatric terminology), Nick was brought down to room 529 for a new s[illegible] of experiments. A tone (T256) similar to the one he had had as a cs for food in room 1[illegible] was made a cs for a faradic shock to the foreleg. 3 seconds after each tone Nick rece[illegible] short faradic shock sufficiently strong to cause him to lift the foreleg and whine slightl[illegible] such daily experiments between 19 March and 16 April Nick reached a level of 65[illegible] on 25 March he gave a positive cr to 65% of the 20 repetitions of T256 used on that d[illegible] and by 15 April he had reached 100%. A differentiation was then introduced between T2[illegible] (+) and T512 (—). This routine continued to 20 June 1942. The differentiation [illegible] perfect only on one day during 1942 (14 May) after about 186 repetitions of the negat[illegible] tone with the positive.

His behavior in these experiments was markedly different from that which had bee[illegible]

[illegible] the experimental room since 1932—before the neurosis. He was now generally [illegible] the camera, there was very little restlessness or overactivity, no barking, no [illegible] breathing was much quieter, there was only slight panting not nearly so marked [illegible]. In marked contrast to his behavior in the old camera, where sexual erections [illegible] nearly every day, there were no sexual erections with the new routine. He stood [illegible] slightly tucked, and whined to each faradic shock but very little in the intervals. [illegible] the pathological sexual erections were absent in the new environment, sexual [illegible] to adequate stimulation were much more prolonged than in the old environment. [illegible] from day to day, however, was still a prominent feature.

[illegible] March. "In room 529 Nick runs around with slight panting, grovels at my feet, [illegible] me, rolls on back, has erection lasting for 3-5 seconds, runs into camera while [illegible] is on the stand and jumps up by him, tucks his tail, stands quiet there, looks [illegible] the floor. There is no whining, only occasional panting. In contrast to his behavior [illegible], Nick has become much quieter working in 529."

[illegible] April. "Nick up to this time had daily repetitions of only the positive cs (T256) to [illegible] shock, and on 15 April he reached a level of 85-100% correct responses to the [illegible]. On 17 April a differentiation was begun between T256 (+) and T512 (—). By [illegible] he had a fair differentiation—80% to T256 and 0% to T512. Subsequently there [illegible] loss in differentiation; during May although the inhibitory reactions to T512 were [illegible], the percent of positive crs to T256 fluctuated around 50%, with marked daily [illegible]. Nick was frequently fairly excited. His heart rate on 16 April, for example, gave [illegible] reading of 110, a positive cr of 116 and a cardiac UR of 119. There was thus [illegible] tachycardia to the pain and to the new environment than there had been. The induced [illegible] showed a prolonged duration—around 10 minutes, compared to 3 or 4 min- [illegible] 120. There was little or no evidence of spontaneous erections or pollakiuria during [illegible] period."

[illegible] June, 1942, Nick was brought down to 120 for the first time since 13 January. As [illegible] approached 120 on the elevator, there was loud raucous breathing. In the antecamera he [illegible] so much hyperactivity as he did during 1941 and previously. There was less [illegible], obsessive dashing in and out of the C. But he urinated four times within the [illegible] minutes, he refused the Spratts ovals in both antecamera and C, and there was an [illegible] seconds when he was shown this food; he picked them up and dropped [illegible]. He continued to show preference for visitors and aversion to H.S.; he ran [illegible] first on Mrs. C.W., whom he had never seen before, then on Dr. R.W., then [illegible] laboratory boy C.D. whom he had seen for the first time that day. He came to me [illegible] I called him, and would not go to H.S. even though he called him repeatedly. [illegible] C there was much less hyperactivity except for the panting, the auditory cs (M [illegible]) in striking contrast to their former effect now were practically without influence [illegible] behavior when repeated 3 times.

[illegible] is thus indication that the procedure of using the auditory cs which formerly pro- [illegible] anxiety in 120, as a new cs for a motor defense cr in 529 has extinguished the [illegible] anxiety reactions to the specific auditory signals but it has not abolished the effect [illegible] total environment of 120.

[illegible] July. "14:30 Nick brought to 120. Two students (M. Tunick and Coppola) and a

new laboratory boy (C.F.) all of whom Nick had barely seen before, nine [illegible] as H.S. and W.H.G. Nick first runs to M.T., jumps up with forefeet on her [illegible] Cuppola, then up on me. Does not go to H.S. even when called. Urinates [illegible] 5 minutes. Refuses food in both antechamber and in camera. Panting [illegible] he is in the laboratory. There is not as much hyperactivity, though he still [illegible] camera, jumps up and down on table. The salivary CR to food placed under [illegible] distant) was absent, there was slight salivary UR secretion when food was [illegible] mouth. Cuppola is impressed by improvement of Nick over last fall when he [illegible] auditory signals (Bu, M) Nick gives very little response. The procedure of [illegible] apparently has removed specific effect of auditory signal but not effect of [illegible] ment."

On 19 October, "Nick is lying down quietly in his paddock. On being approached starts barking, giving the normal reactions that the other dogs do. [illegible] asthmatic-like breathing, which alternates with the rapid panting. When brought [illegible] first to the rest at the visitor (B.S.) rather than to W.H.G. During the next [illegible] carried through the halls, he urinated 11 times. When brought into 519 he [illegible] in symptoms. Taken down to 120 he urinates about 5 times in the next 5 minutes. [illegible] increases steadily during the time he is there. He also shows preference for B.S. over W.H.G., running to the former several times but not once to W.H.G. When told to get into the camera, he dashes in and out, jumps up and down from the table, looking down toward the place where the tone originally came from, pausing and then panting and running [illegible] runs excitedly around the room as formerly. There is no sexual erection while in [illegible] room. Nick thus shows the same pattern of disturbed behavior in the dyspnea, the [illegible] and the running activity. The individual auditory stimuli were not tried. His [illegible] this environment is only slightly improved from what it had been, and [illegible] than it was during the April, May and June when Nick was being actually worked [illegible] the defense crs. He has not been experimented upon for 4 months, having remained [illegible] paddock during this time. He is well nourished and in good physical condition."

On 27 October, a male dog Bamech was seen for the first time in the laboratory [illegible] to appear restless in the camera, not to take the food and to show reversal of the [illegible] crs (paradoxical phase). Although Bamech was a stable [illegible] dog, his behavior [illegible] this day was so similar to Nick's that it warrants description. He was [illegible] twisted and turned on the table, urinated about every minute in the antechamber, [illegible] same pattern of scratching with all fours after defecating that Nick had, tugged [illegible] to get back to the paddock, where there was a female in estrus whom Bamech [illegible] stantly around. Bamech, the female and Nick were brought down together [illegible] Nick made advances toward the female and attempted to mount her, and she [illegible] playfully at him. The behavior of Bamech and Nick in the antechamber with the [illegible] very similar—pollakiuria about every 30 seconds (undisturbed by the [illegible] menter). Nick also defecated on the floor with a marked erection showing the same [illegible] of scratching and spinning as previously noted. Neither Nick nor Bamech would take food when sexually excited, although the female would—a difference in male [illegible] noted previously.

[illegible] of the behavior of [illegible] under sexual stimulation to that of Nick in the [illegible] of conflict is so striking that it will be discussed separately in the next chapter.

1943

On 11 January, "Nick brought to 120 for demonstration. Runs and jumps [illegible]; [illegible] Vivado and M.F. neither of whom he had seen before, once on W.H.G. [illegible] time on H.S. Urinates several times in the antecamera. When first brought [illegible] he accepts food, even during the auditory csi, but not after he has been leashed [illegible]. Nick gives almost no defensive movements to the auditory csi. In general he is [illegible], though there is still the raucous breathing. His improvement may be due to [illegible] procedure of using the csi in another connection (*v. supra*) or advancing [illegible] 52).

On [illegible] February, "Nick has not been used in routine experiments since 19 June 1942 [illegible] differentiation between T256 (+) and T512 (—) was about 70% to the positive [illegible] to the negative tones respectively (the tones having csi for a faradic shock to [illegible]. Tested after this 8 month interval the retention of the motor crs was practically [illegible] 90% responses to the positive tone and 0% to the negative. As a matter of fact [illegible] was even better after this interval; for in a few days he reached the level of [illegible] and 0% and maintained this differentiation regularly. The cardiac crs were not [illegible] after the interval until 9 March, 1943, when they showed a differentiation of 164 [illegible] with the positive cs and 151 with the negative cs, i.e., the positive cardiac cr was [illegible] more than its control and the negative cardiac cr was 109% more than its control, [illegible] crs being on the same day 100% and 0% to positive and negative csi respectively."

The explanation of the improvement in Nick's performance in the spring of 1943 even [illegible] intervening practice may be considered due to one of several causes: 1) he may have [illegible]" during the interim, a phenomenon described by William James (*60*) and given a [illegible] basis in the experiments of Light and Gantt (*73*) who showed by paralyzing a leg [illegible] crushing of the anterior nerve roots) that practice is not necessary for formation [illegible]; or 2) his improved record may be a result of his general improvement; 3) possibly [illegible] factor may play a role since in 1943 Dr. Freile worked with him instead of H.S. or W.H.G., and with Dr. Freile with whom he had no previous associations he had already [illegible] more friendliness than to H.S. or W.H.G. This factor is to be investigated.

On 16 and 17 March 1 cc. adrenalin 1:1000 was injected intramuscularly, and several [illegible] April 1 cc. intravenously in both Nick and stable dogs to determine its effect on the [illegible]. This is an enormous dose for a normal dog and even proved fatal to two healthy dogs. In Nick there was only a slight impairment of both the motor and the cardiac crs, viz., a [illegible] in the positive motor responses from 100% (control) to 80% (adrenalin) with the intravenous dose. The respiratory and cardiac rates were only slightly changed. In the [illegible] stable dogs there were violent alterations in respiration, cardiac rate, and in the motor [illegible]. In Connie, e.g., the respiration was increased to about 300, the cardiac rate doubled and the positive crs reduced from 100% (control) to 50% (adrenalin). The differentiation between the positive and negative cardiac crs was also destroyed. The intramuscular injection [illegible] no effect on Nick but in Connie the differentiation was impaired also by this

method. Following the [illegible], C[illegible] which showed improvement. These results [illegible] cated in figs. 19a and 19b.[21]

On 12 August, When Nick was taken from his paddock to be [illegible] to the farm in Virginia, he jumped obediently into the open cage and lay quietly. On arrival [illegible] he was much more friendly to me than he had been the previous times he was brought [illegible] he was usually quiet—less active than in [illegible]. During the 6 weeks in the country he was [illegible] at the farm, almost [illegible]. He would be friendly. He hardly followed me around on the farm [illegible] after the car, however, at a speed less than formerly—12 miles per hour was his limit, compared to 15 miles per hour on his previous visits. Nick began to show signs of [illegible] he was apparently partially deaf, spent much time sleeping, snoring loudly, and [illegible] easily aroused, although occasionally he seemed rather restless, continually [illegible]

Some of his old symptoms manifested themselves but not to a marked degree. [illegible] was more frequent than in most dogs but rarely occurred at the farm although it had been [illegible] in the laboratory. No abnormal sexual symptoms appeared nor was there evidence of interest in females. He occasionally fought with other dogs [illegible] as previously. Nick's abnormalities were noted by several people who had not seen him previously. For example, two boys aged 7 said, speaking of his rapid breathing, "Gee, that dog certainly does breathe funny." On another occasion when Nick suddenly ran from the [illegible] of a wood chopper, the latter remarked, "That dog must be gun shy."

Though Nick showed no evidence of being cooperative and as friendly [illegible] towards other dogs, nevertheless he still appeared to learn rapidly. For example, although he would not come into the [illegible] when called to do so, he would immediately run to the car whenever anyone got in or blew the horn in preparation to leave.

In connection with Dunbar's observations concerning the proneness of certain types to accidents, it is interesting that Nick showed this tendency during 1943 as well as previously. In 1937 he frequently got tangled in his chain, binding and hurting himself. In [illegible] the farm, he twice fell into an abandoned privy where he could not extricate himself and where he remained for some hours until he was located by his barking. He would [illegible] knock into things, get under people's feet, run into machinery, etc. On one occasion at night he followed my car without my knowledge, but as he could not overtake me, I met him on my return homeward. After passing him going in the opposite direction I turned around and went back, but he again had recognized my car and was again running toward me. I put on the brakes, but he continued running into the car which knocked him down and dragged him along, resulting in two scalp wounds. However, he trotted on [illegible] pace, so that I did not find him until I had also arrived.

Nick came to an end in January 1944 perhaps appropriate to his life—he was killed accidentally in a fight with another dog. An autopsy showed slight bleeding points on the gastric mucosa but without definite ulceration. Gross examination of the organs [illegible] indicated they were normal. Detailed studies have yet to be made.

[21] A further analysis of these experiments will be given in a subsequent paper dealing with the effect of [illegible] on behavior. Sufficient experiments have been performed [illegible] however, to indicate that our results are statistically reliable.

## VI. SUMMARY OF OBJECTIVE SIGNS ACCORDING TO PHYSIOLOGICAL SYSTEMS

THE FOLLOWING epitome and classification of symptoms is intended to give a systematized picture of the behavior, rather than to isolate the symptoms as independent reactions. That each plays a role in the integrated response and the fact there are reciprocal relations is evident from the previous account.

The abnormal appearance of the symptoms consisted in 1) either too much or too little response in the given situation, i.e., too much excitation or inhibition; 2) appearance of entirely new reactions. The marked character, regular manifestation, and stereotypy of pattern of many of the symptom-complexes if they had occurred in the human patient, would probably have led to diagnoses of cardiac, respiratory, urinary, sexual, etc., neuroses.[1]

But as it is the purpose of these experiments to trace the forces at work in producing and maintaining the nervous disturbance rather than to make a diagnosis, clinical correlations will be kept subservient to a presentation of the objective manifestations and their relationships.

### 1. ACTIVITY;[2] METABOLISM

Marked changes in activity have been reported during the presence of various animals in the environment of conflict, ranging from rigidity and catalepsy to greatly exaggerated manic-like behavior (Pavlov, Liddell, Maier, Masserman, Dworkin). In our series of disturbed dogs during the situation of conflict, one of them would fall into a deep slumber with complete relaxation lasting 15-30 minutes. Such sleep is different from the brief sleep often accompanying normal inhibition. Pavlov has reported many such instances; H. G. Wolff (*110*) and I had a dog (Kompa) who regularly fell asleep on the 7th to 9th second after the beginning of the inhibitory metronome. Nick however showed almost maniacally exaggerated activity whenever he was brought into the experimental camera—rushing in and out of the camera, jumping upon the table and running about the room. His activity was in marked contrast to that of normally hyperactive dogs such as Billy, who would playfully run to all parts of the room, while Nick's

[1] By the use of this term I do not intend to do more than make a superficial analogy to what is referred to under the ill defined term *neurosis*. Since it is impossible in the dog to use any system using subjective feelings—often the main criterion in the human—it is important to have a clear picture of the objective manifestations ("signs").

[2] The method of recording 24 hour activity has been adapted by Muncie and Gantt from that used by Richter (*94*) in the activity of rats; it records movement in a horizontal but not in a vertical direction.

running was mostly in and out of the camera in a stereotyped manner. A[illegible] camera represented conflict for Nick, this may be likened to the compu[illegible] havior of patients. Nick's running was usually accompanied by rapid [illegible] breathing, giving the impression of an animal being pursued.

Not only in the camera but in his 24 hour activity, measured in th[illegible] Nick showed exaggerated activity—much greater than that of any oth[illegible] with wide fluctuations from day to day. As previously stated Nick's runn[illegible] not equally affected by the same factors that determined the running of t[illegible] mal dogs, i.e., there was a low correlation coefficient between Nick and th[illegible] animals. Nick's activity has been approximately the same in pattern du[illegible] whole time that it has been recorded, from 1934 to 1941, with several pe[illegible] diminished activity, parallel to his improved behavior. Outside of the lab[illegible] on the farm, though he was active, most of the symptoms of abnormal-like a[illegible] were absent; also the 24 hour activity was reduced and more nearly normal [illegible] sexual activity. The increase of the activity seemed to parallel the abnormal [illegible] havior in the camera.

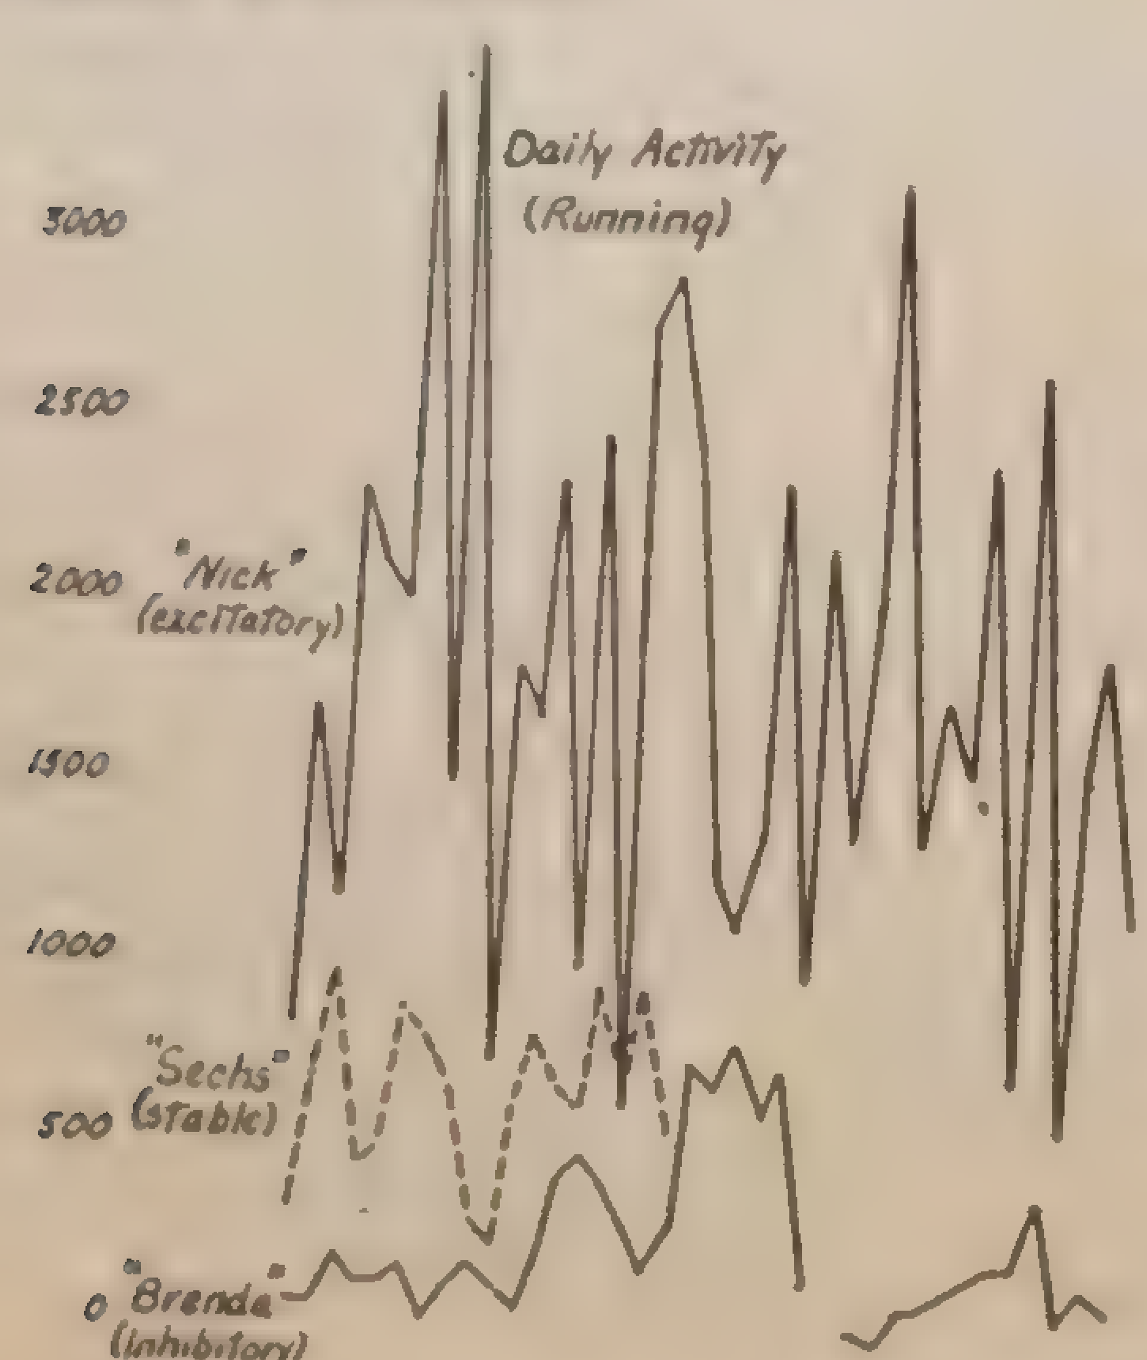


FIG. 15. Samples of activity from Nick (ex-[illegible]) Sechs (stable) and Brenda (inhibitory).

Below are samples of the 24 hou[illegible] tivity from Nick, in comparison wi[illegible] normal dogs—one an extreme q[illegible] stable phlegmatic type (Sechs) and [illegible] other a pathologic inhibitory type (B[illegible] da) (fig. 15). Although quantitative [illegible] tivity records were not made on N[illegible] prior to 1934 and no comparison of [illegible] 24 hour activity is possible before [illegible] after the development of the neu[illegible] it was evident that the behavior [illegible] camera showed greatly augmented [illegible] tivity after the conflict.

An interesting aspect of the 24 [illegible] activity is the correlation coeffi[illegible] among the normal dogs, as contrast[illegible] with the correlation between Nick [illegible] the normal dogs. Three of the acti[illegible] cages (nos. 1, 2, 3) are alongside each other and in the open air so that the d[illegible] can see and hear one another though they are separated by gratings. Cage 4 how[illegible] ever is an inside one and completely separated from the other three. A correlati[illegible] was made between Nick and a normal dog when Nick was in the cage alongsi[illegible] the other dogs and also when he was in cage 4 separated from the normal dog[illegible] Positive correlations were found among all the normal dogs, i.e., when the a[illegible]

ity of one normal dog increases[3] the activity of the other normal dogs also increases, the fluctuations move in the same direction, but the activity of Nick (as well as of another neurotic dog, Brenda) is independent of the others (92).

Table 18 and fig. 16 show these relationships. Vera, Billy, Ephraim, and Pat always showed normal behavior with the exception that Pat on one occasion appeared to suffer a slight disturbance of behavior.

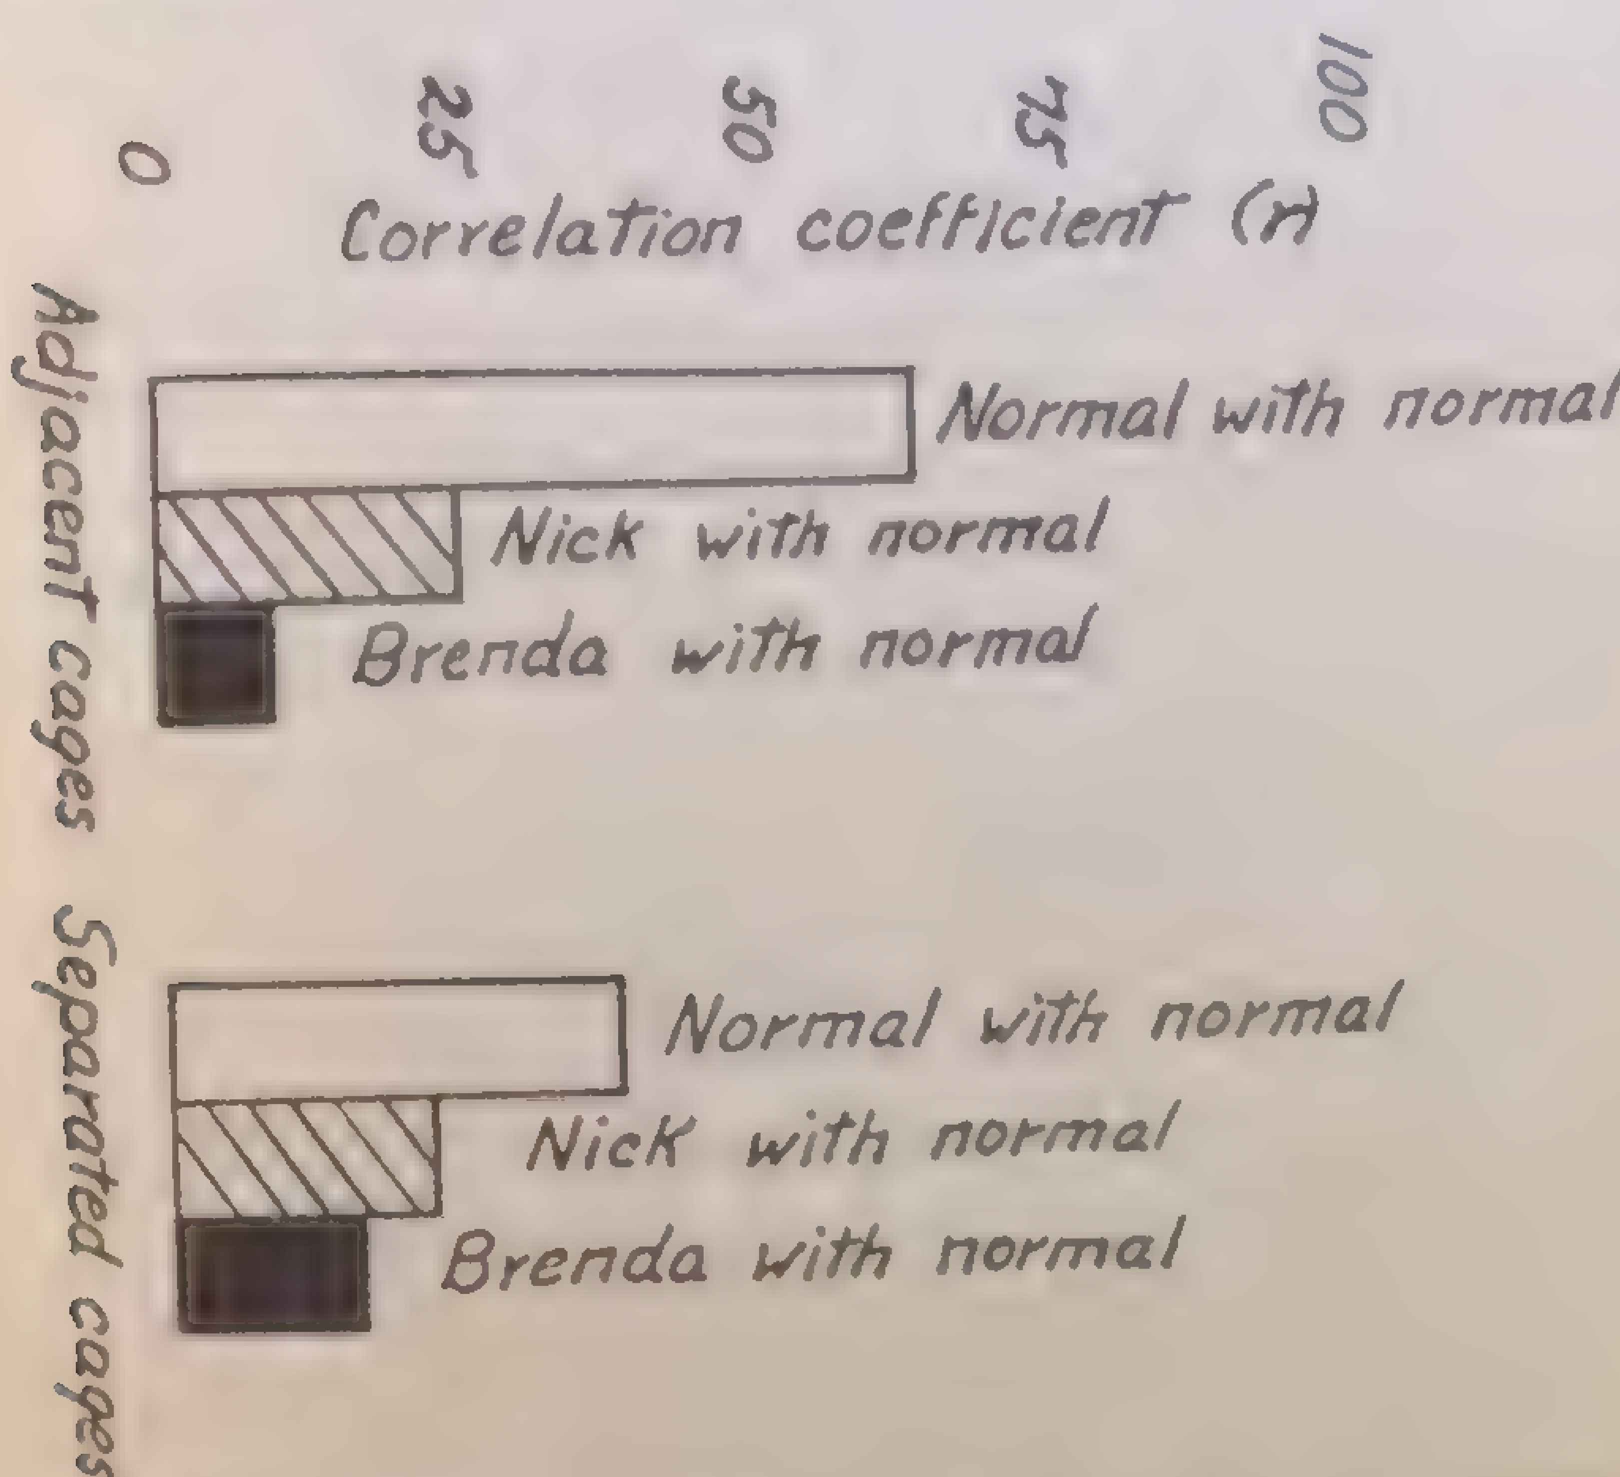

FIG. 16. Activity correlation among stable dogs and correlation of labile dogs (Nick and Brenda) with stable dogs

From Table 18 it can be seen that there is a definite positive correlation among all the normal dogs when they are in adjacent outdoor cages, but that there is no correlation between Nick and three normal dogs nor between Brenda and two normal dogs regardless of whether they are in adjacent or separated cages. A reference to statistical Table 20 indicates that in most of the cases except Nick's there is less than one out of 100 or more chances that the high correlation coefficients could be due to random fluctuations. The fact that Nick's activity, i.e., the distance that he runs daily, is independent of that of his neighbors, even though he is in the same environment with them is in accordance with his aloofness from other dogs and his marked lack of rapport. This was observed on many occasions, e.g., in his early life (1932) when Nick in contrast to Fritz and other dogs together in the paddock was seen to shun a female in estrus when he was with a group of other dogs.

[3] Whether this increase and fluctuation is mainly due to humidity, temperature or other meterological changes, as suggested by Peterson, cannot at present be answered (92).

The coefficient of variability (v) for the daily fluctuations was: P[illegible] Sechs—44, Fritz—44, Ephraim—50, Billy—50, Nick—48, Brenda—50. T[illegible]

TABLE 18

CORRELATION COEFFICIENTS FOR ACTIVITY

| Name | Adjacent Outdoor Cages | | | Separated (Outdoor-Indoor Cages) | | |
|---|---|---|---|---|---|---|
| | r | N (no. cases) | P | r | N | P |
| *Normal dogs* | | | | | | |
| Billy-Polkan | 0.21 (Nov. '35–Feb. '36) | 65 | .05 | | | |
| Sechs*-Ephraim | 0.28 (Jan. '38–Apr. '38) | 62 | .02 | 0.32 (Apr. '38–June '38) | 78 | [illegible] |
| Ephraim-Pat | 0.38 (May '37) | 31 | .02 | | | |
| Fritz-Ephraim | 0.5[illegible] (May '37) | 50 | .01 | | | |
| Billy-Ephraim | 0.55 (Dec. '37–June '38) | 141 | .01 | | | |
| Vera*-Pat | 0.56 (Nov. '35–Feb. '36) | 30 | .01 | −0.12 (Oct. '36) | 13 | [illegible] |
| Fritz-Billy | 0.57 (May '37) | 51 | .01 | | | |
| Sechs*-Billy | 0.72 (Jan. '38–Apr. '38) | 60 | .01 | 0.55 (Apr. '38–July '38) | 89 | [illegible] |
| *Normal-Neurotic dogs* | | | | | | |
| Nick*-Polkan | 0.43 (Dec. '36–Apr. '37) | 91 | .01 | 0.56 (Nov. '35–Dec. '36) | 39 | [illegible] |
| Nick-Pat | 0.13 (May '37) | 31 | .1 | | | |
| Nick-Fritz | 0.19 (Dec. '37–Jan. '38) | 42 | .1 | | | |
| Nick*-Billy | 0.00 (Apr.–July '38) | 59 | .1 | | | |
| Nick*-Ephraim | 0.02 (Apr.–June '38) | 49 | .1 | 0.00 (Dec. '37–Apr. '38) | 104 | .1 |
| Nick*-Sechs | | | | 0.08 (Jan. '38–Apr. '38) | 66 | .1 |
| Nick-Sechs* | | | | 0.50 (Dec. '37–Apr. '38) | 56 | .01 |
| Brenda*-Sechs | | | | 0.28 (Apr.–July '38) | 66 | .02 |
| Brenda-Connie | 0.09 (11 Nov. '40–5 Jan. '41) | 27 | .1 | 0.14 (28 June '40–10 Nov. '40) | 39 | .1 |

*Normal dogs (r)*

Median of normal dogs: in adjacent outdoor cages (8 pairs) = .53
in separated outdoor cages (3 pairs) = .33

*Neurotic dogs (r)*

Median of Nick with normal dogs: in adjacent cages (5 pairs) = .19
in separated cages (5 pairs) = .18

Median of Brenda with normal dogs: in adjacent cages (1 pair) = .09
in separated cages (1 pair) = .14

* Indicates which dog of the pair is in indoor cage when separated.

A correlation coefficient (r) of 1.0 indicates complete agreement, while when r approaches zero the [illegible] of one dog is entirely independent of the activity of the others. The nearer r approaches 1.0 the more [illegible] fluctuations of the activity in the two dogs for whom the r is measured, are apparently influenced by the same factors. In the table where P is .1, it means a definite correlation cannot be established between the two dogs.

... variability is contradictory to the observations on the variability ... characteristics of the neurotic.

Though insufficient day and night readings have been made on our neurotic ... to settle the question of nocturnal restlessness, it is possible that the lack of ... in Nick may have been a result of increased nocturnal activity, as ... out by Liddell in neurotic sheep. This was observed on many occasions, ... in his early life (1932) when Nick, in contrast to Fritz and other dogs to... in the paddock, was seen to shun a female in estrus when he was with a group of other dogs.

A striking parallel between behavior and the 24 hour activity record was seen ... year old female dog, Brenda, who had been raised in the country as a pet, ... to the city in the autumn of 1939. On 28 June, 1940 Brenda was transferred to the laboratory and for the first two weeks she barely moved from one ... in her cage except to walk a few feet to the food bucket. After being in the laboratory for 3 weeks her activity increased only slightly. On 24 July, 1940 she was taken to the farm where she remained until October 29, when she was returned to the laboratory. The activity record was parallel to that seen in the summer: for the first 2 weeks she lay motionless continually in one place. After 3 weeks the activity gradually increased again. The general behavior of this dog was parallel to the activity record. When she was brought out of her cage into the room she stood absolutely motionless in one spot with tail tucked between her legs, head down and back arched, and no matter how much she was coaxed, called, or offered food, she would not budge. The dog's behavior was no more friendly to me, her master, than it was to the others in the laboratory. The dog was taught with difficulty to eat from the food box. On those days when her activity was greatest she appeared more friendly and ate more readily.

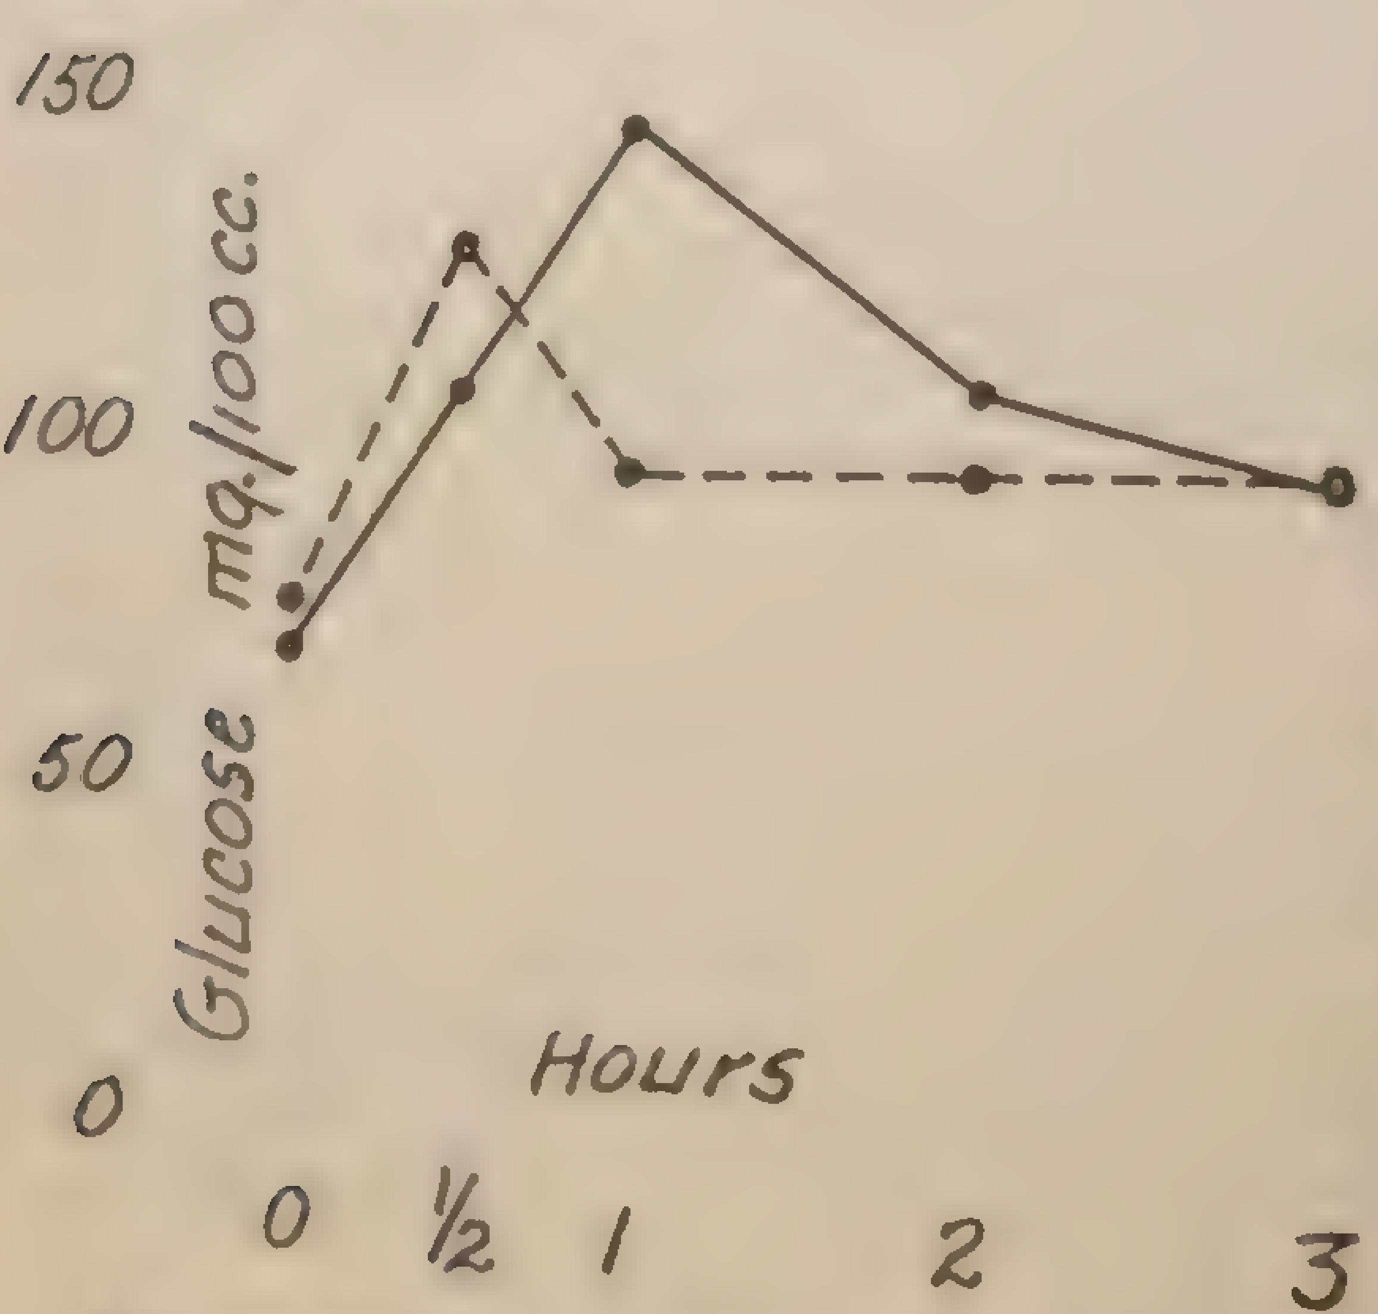
With another dog, Blue, as a result of a natural emotional shock in 1932 it was noted that his posture was the same as Brenda's and that his observed activity was much subdued, (at that time the 24 hour activity was not recorded). Both Brenda and Blue were hypoactive animals and under stress the activity was still further diminished. Nick, a hyperactive dog, showed, on the other hand, decreased activity when his behavior was more nearly normal, e.g., after sexual activity. The change in activity under stress therefore varies with the type of dog.

The activity of the normal animal has been shown (*44*) to bear some correlation with both cr and UR activity. However notwithstanding the large amount of work that has been done on the subject and such highly interesting and suggestive observations as those of Peterson (*92*), the whole question of the meaning of activity is undoubtedly a most complex one, dependent upon many factors as shown by the extensive experiments of Richter on rats.

Summarizing the observations on 24 hour activity, a conflict may either increase

or decrease the activity depending upon the type of dog. Other factors, [illegible] variability in the activity, were only slightly different for the normal [illegible] abnormal dogs. The absolute extent of the activity is unimportant, [illegible] is significant and also the lack of correlation (rapport: ) of the [illegible] normal dogs.

*Blood sugar tolerance* tests were performed on Fritz, Peter and Nick [illegible] 1933, on the initiative of Oskar Diethelm. Diethelm (*15*), E. M [illegible] [illegible] and others have reported a correlation in patients between emotional [illegible] and the shape of the curve representing per cent of sugar in the blood [illegible] administration of a given weight of glucose on a fasting stomach. The tests [illegible] made during the period of increasing differentiation in the experiments [illegible] three dogs. 100 grams of glucose were given orally in solution, allowing the [illegible] to drink it in the morning on a fasting stomach immediately before the experiment, and blood samples were taken before administration and ½ hr., 1 hr., [illegible] and 3 hrs. thereafter. The test was repeated 9 times on Fritz, 16 on Peter [illegible] on Nick (Table 19).



[illegible] Blood sugar tolerance in Nick outside environment of conflict (dotted line), in environment of conflict (solid line).

Although it is not possible to see a correlation in the type of curve and the daily [illegible] disturbance in the animal, [illegible] conclusions may be drawn, [illegible] there is a difference in the blood sugar tolerance curve for Nick when he is outside the environment of conflict (in his paddock) and when he is in the experimental room. This is shown in Fig. 17a. The curve for the blood sugar tolerance with Nick in the paddock is the average of [illegible] experiments; that with Nick in the camera, average of [illegible] experiments. This comparison indicates, according to the [illegible] Diethelm (15) that the dextrose tolerance for Nick in the environment of conflict is more nearly like that seen in emotional states of patients, particularly those of tension and anxiety. Secondly, the pattern plotted from the average figures of all the experiments is correlated with the extent of the disturbance in each animal (Fig. 17b). The pattern of Nick has the greatest rise; it is more nearly similar to the curves seen in states of anxiety while the curves for Fritz and Peter [illegible]

TABLE 19
BLOOD SUGAR TOLERANCE

| [illegible] Test Days) | | | Peter (15 Test Days) | | | Nick (20 Test Days) | | |

nearly identical. Comparing the means for each hour in the three dogs it appears that the curve for Nick is definitely of a different type than those for Peter and Fritz; comparing the hourly means of one dog with the other by Fisher's method, the P values[4] are as follows (Table 20). The table shows a significant difference

TABLE 20
P VALUES

| | 0 Hour | ½ Hour | 1 Hour | 2 Hour | 3 Hour |
|---|---|---|---|---|---|
| Nick and Fritz | .01 | between .1 & .05 | .01 | .01 | |

| Fritz and Peter | .01 | .3 | between .2 & .1 | .6 | |

[4] P = probability, indicating where P is less than .05 that there is a real and not a chance difference between the two dogs. For calculation of P see Fisher (27 p. 114).

between the curves for Nick and the other two dogs except for the ... no significant difference between Fritz and Peter.

Diethelm says of the curves, "Nick was the only dog whose blood ... ance picture corresponds to patients who develop mounting tension, ... (personal letter).

The blood sugar tolerance is a measure of rate of absorption as well ... zation of sugar by the organism. It is thus partly dependent upon intestinal ... ity and other ... factors.

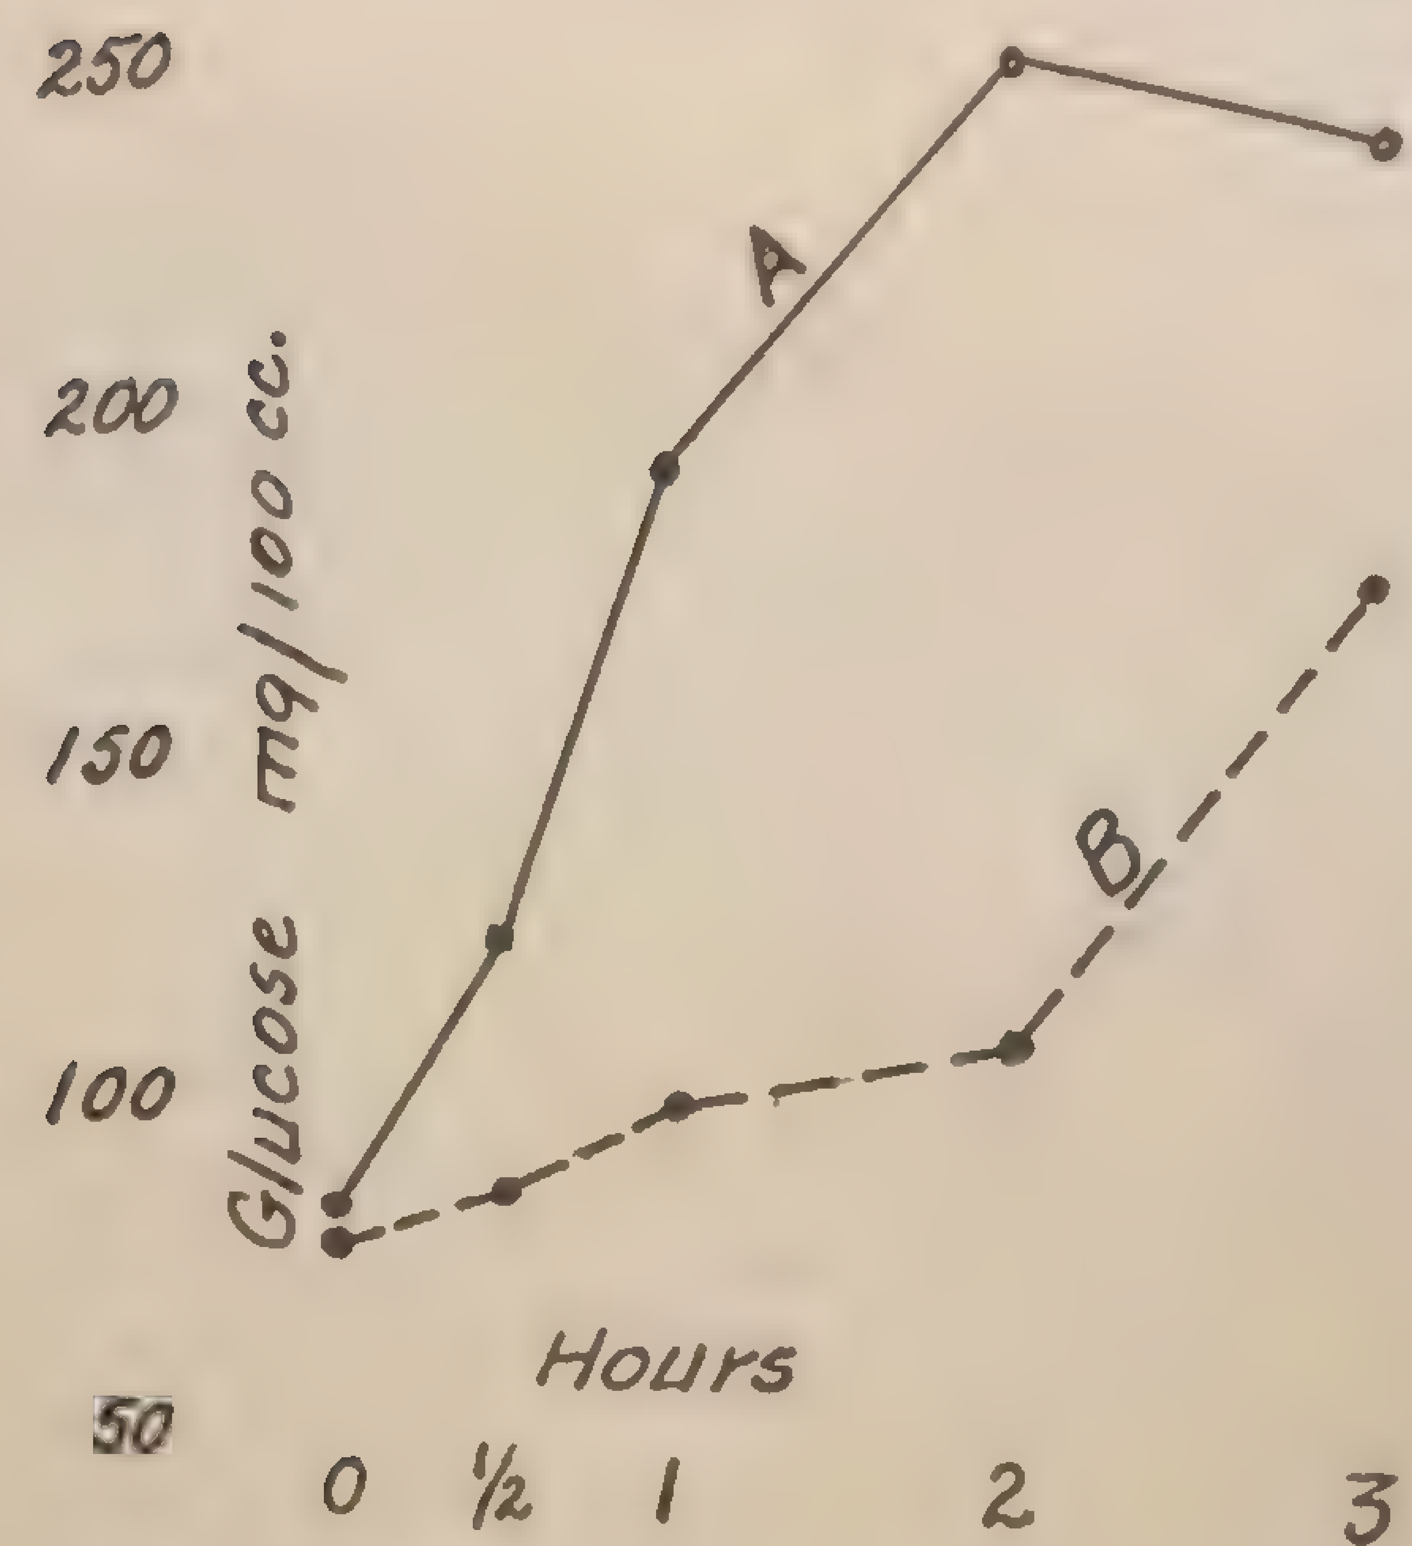

FIG. 18. Comparison of curves (A) after injection of adrenalin plus 100 gms. glucose and (B) after injection of adrenalin alone.

Fig. 18 gives a comp... the curves for blood ... after subcutaneous injecti... adrenalin (1 cc.) with 10... of glucose given orally ... after injection of adrenali... cc.) alone. It is seen that the ... ter curve is approximately ... summation of the curves ... duced by the adrenalin and ... curve produced by 100 gram... glucose fed alone. Dworkin ... obtained the same results in ... Figs. 17a and 17b indicate ... Nick has more sugar to han... (perhaps by liberation throu... the action of adrenalin) but ... he handles it just as well ... the other two dogs" (C. ... Brooks).

Remarkable and interesting data were obtained in Nick and other dogs dur... a study undertaken in 1932 (with Diethelm) and continued in 1943 (with ... Freile) on the effect of adrenalin on the crs. Table 21 shows in another d... (Kompa) a striking resemblance between the effect on the crs of fright an... adrenalin injection. Besides the conclusion that adrenalin as well as emoti... disturbances impair differentiation, these facts together suggest but by no m... prove that the secretion of adrenalin may play a role in the anxiety state of N... Further experiments strengthened this view. In 1943 Freile and I showed th... the intravenous injection of adrenalin (.5 cc. to 1 cc. 1:1000) produced in sta... dogs not only great increases in both the cardiac and respiratory rates (respirati... as much as 300 per minute, with doubling of the heart rate) but a marked

[illegible] balance, while in Nick even the largest dose [illegible], sufficient [illegible] dogs) exerted only a slight disturbance on respiration, cardiac [illegible] the crs. In both dogs the impairment became worse with subsequent [illegible] and lasted for many days after five injections. In view of the fact that [illegible] is destroyed by the tissue within a few minutes, the central nervous [illegible] may undergo severe damage. (See figs. 19a, 19b).

TABLE [illegible]

ACTION OF ADRENALIN COMPARED WITH FIGHT ON DIFFERENTIATION

| | +CR | −CR | No. Observations |
|---|---|---|---|
| [illegible] | 115 | 0 | 16 |
| [illegible] Adrenalin (1 cc.) | 150 | 70 | 12 |
| [illegible] | [illegible] | [illegible] | 4 |
| [illegible] | [illegible] | [illegible] | 8 |

[illegible] tissues are denervated and [illegible] deprived of adrenalin-like sub[illegible] they become more sensitive to [illegible] (Cannon and Rosenblueth [illegible]). Also where acetylcholin occurs in [illegible], as around the heart, denerva[illegible] causes the disappearance of the neu[illegible] cholinesterase as shown by Dale [illegible] students. Hence if the sensitivity [illegible] changed in one direction perhaps [illegible] changed in the opposite direction [illegible] sensitivity. From these facts [illegible] observations on Nick it may be [illegible] that the daily adrenalin [illegible] of Nick is of such magnitude as to render him immune to doses that pro[illegible] a profound disturbance and even [illegible] in other dogs (Freile). The fact that we previously found a tolerance in dogs to the effect of repeated adrenalin [illegible]jections on hyperglycemia also supports this view (36).

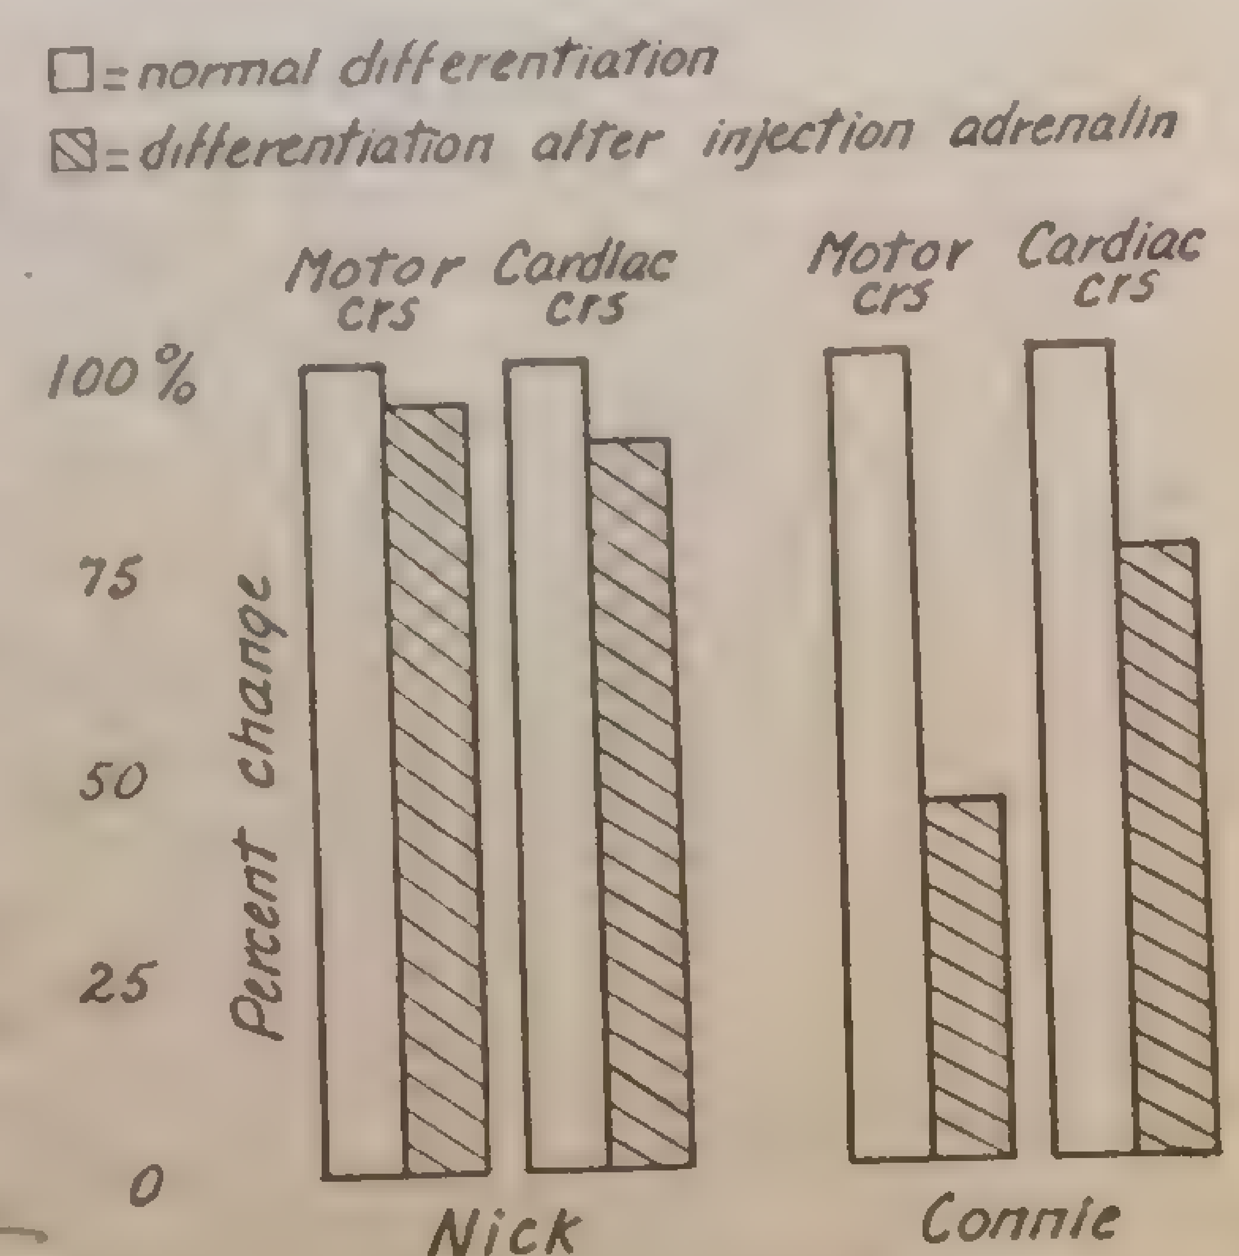

FIG. 19a. Impairment of differentiation (measured by both motor and cardiac crs) caused by adrenalin injection in labile (Nick) and stable (Connie) dogs, expressed in percent of normal.

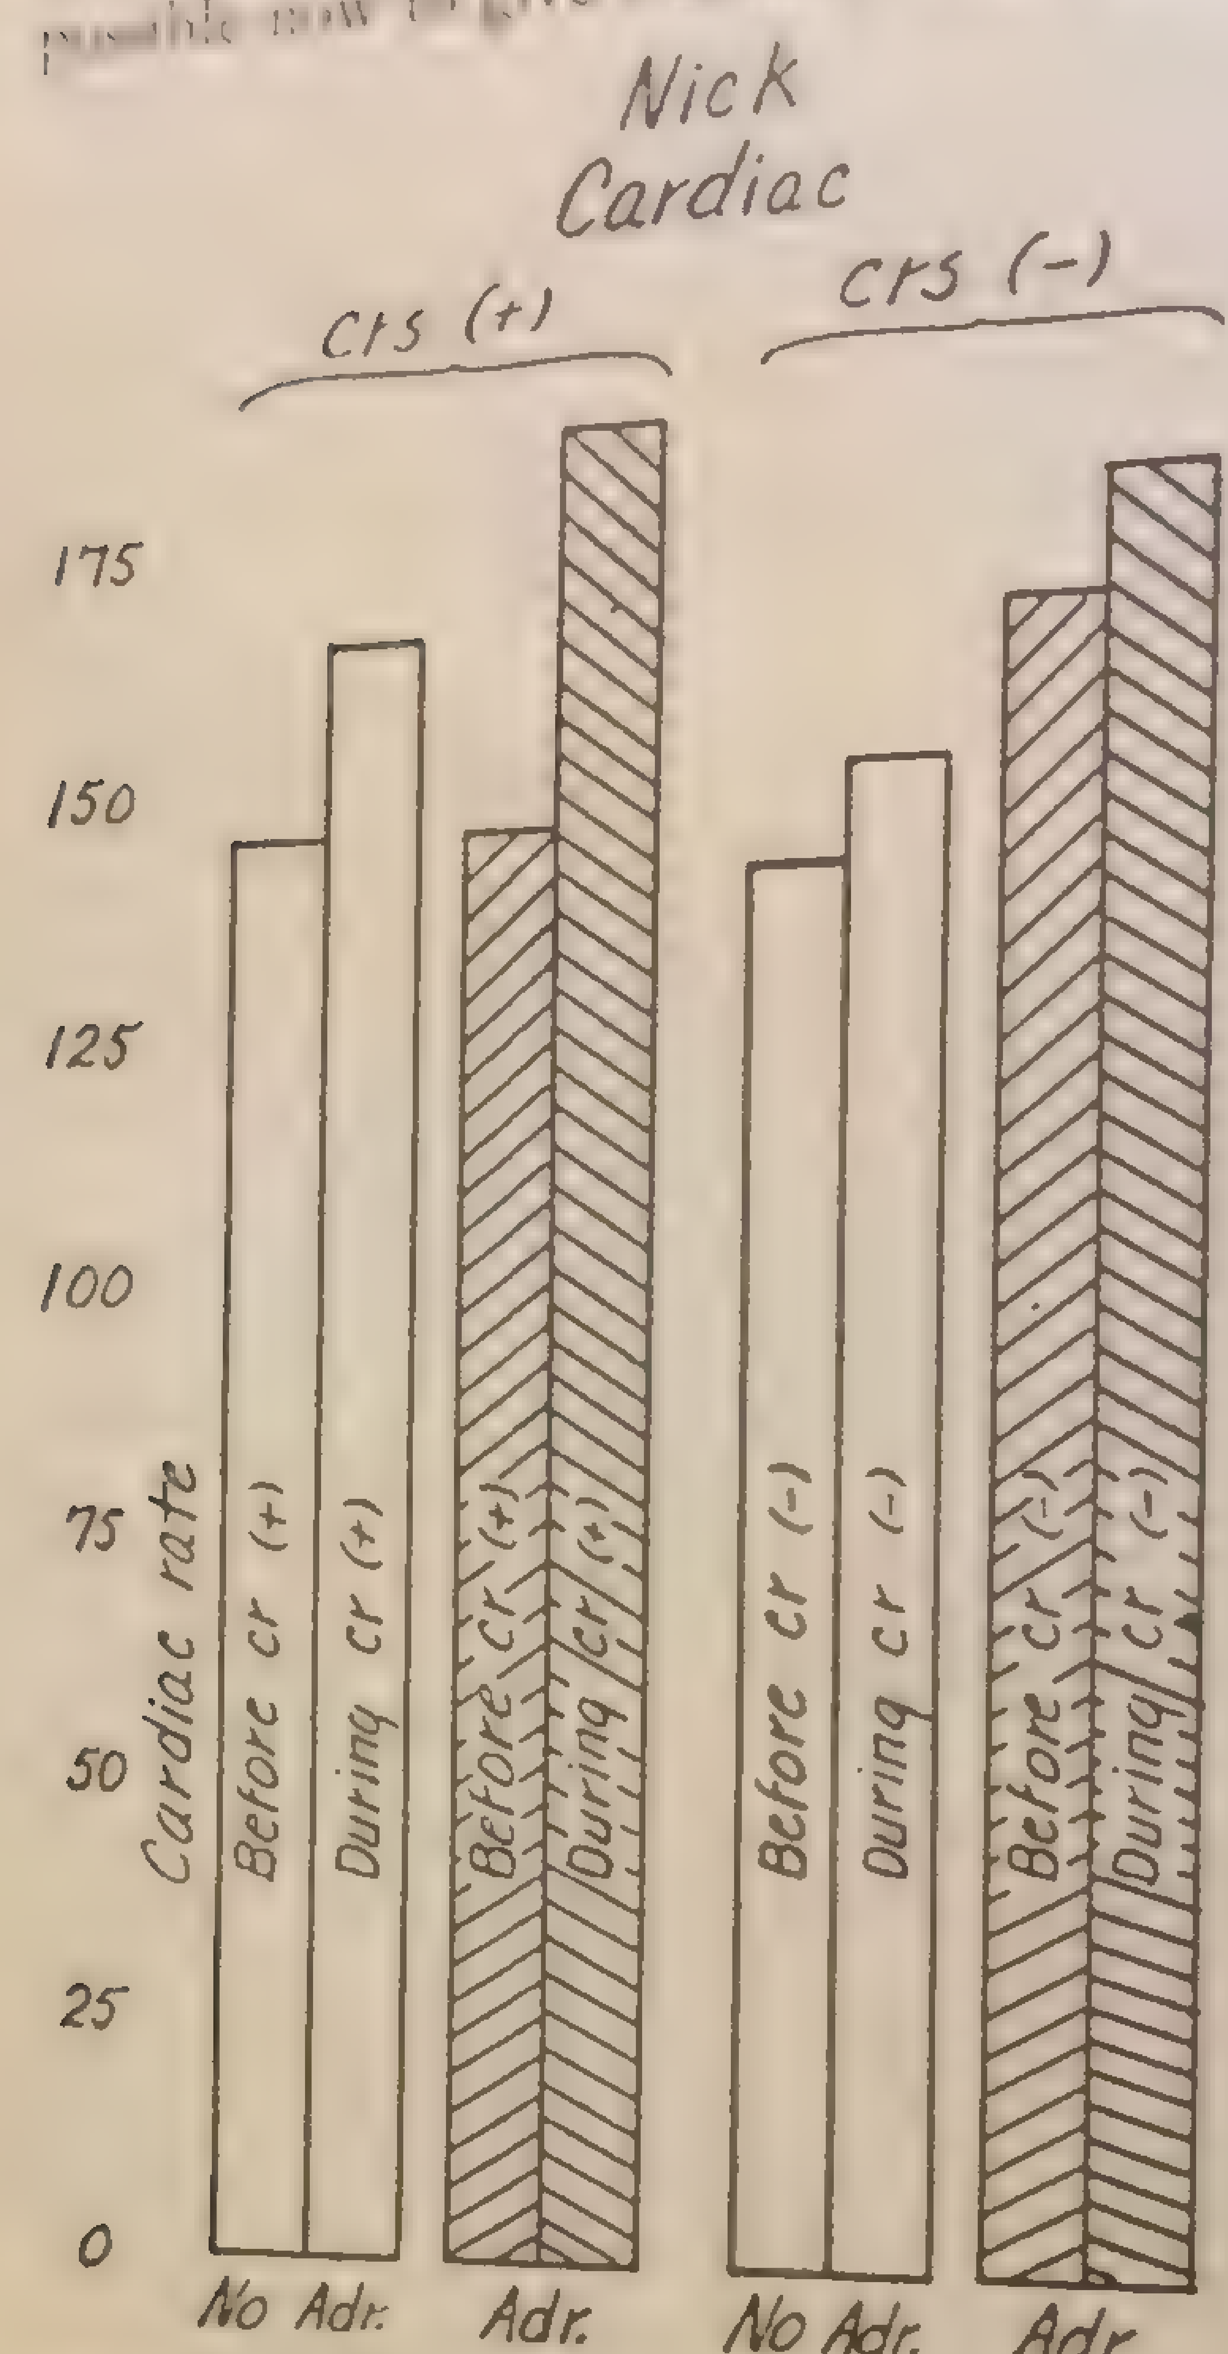
Brooks, on the other hand, proposes that there may be in Nick a more active compensating reflex mechanism such as that represented by the carotid sinus, than in those other dogs who show increased sensitivity to the adrenalin. The fact that in animals (rabbits) with a pre-existing hyperglycemia adrenalin does not have [illegible] great an effect as when there is no hyperglycemia (Dworkin [91]) is consistent with the above explanation of Brooks as to why adrenalin does not have so much

effect upon Nick as upon normal dogs. However on the basis of the [illegible] possible now to give a definite final explanation of the mechanism.

As mentioned in Chapter [illegible] variability is a measure of [illegible]ogy. A comparison of the standard deviation ($\sigma$) and of the coefficient of variation ($v$) [illegible] dogs (Table 19) reveals that [illegible] lowest for Fritz, intermediate for Peter and by far the highest for Nick. This, as has been stated [illegible]



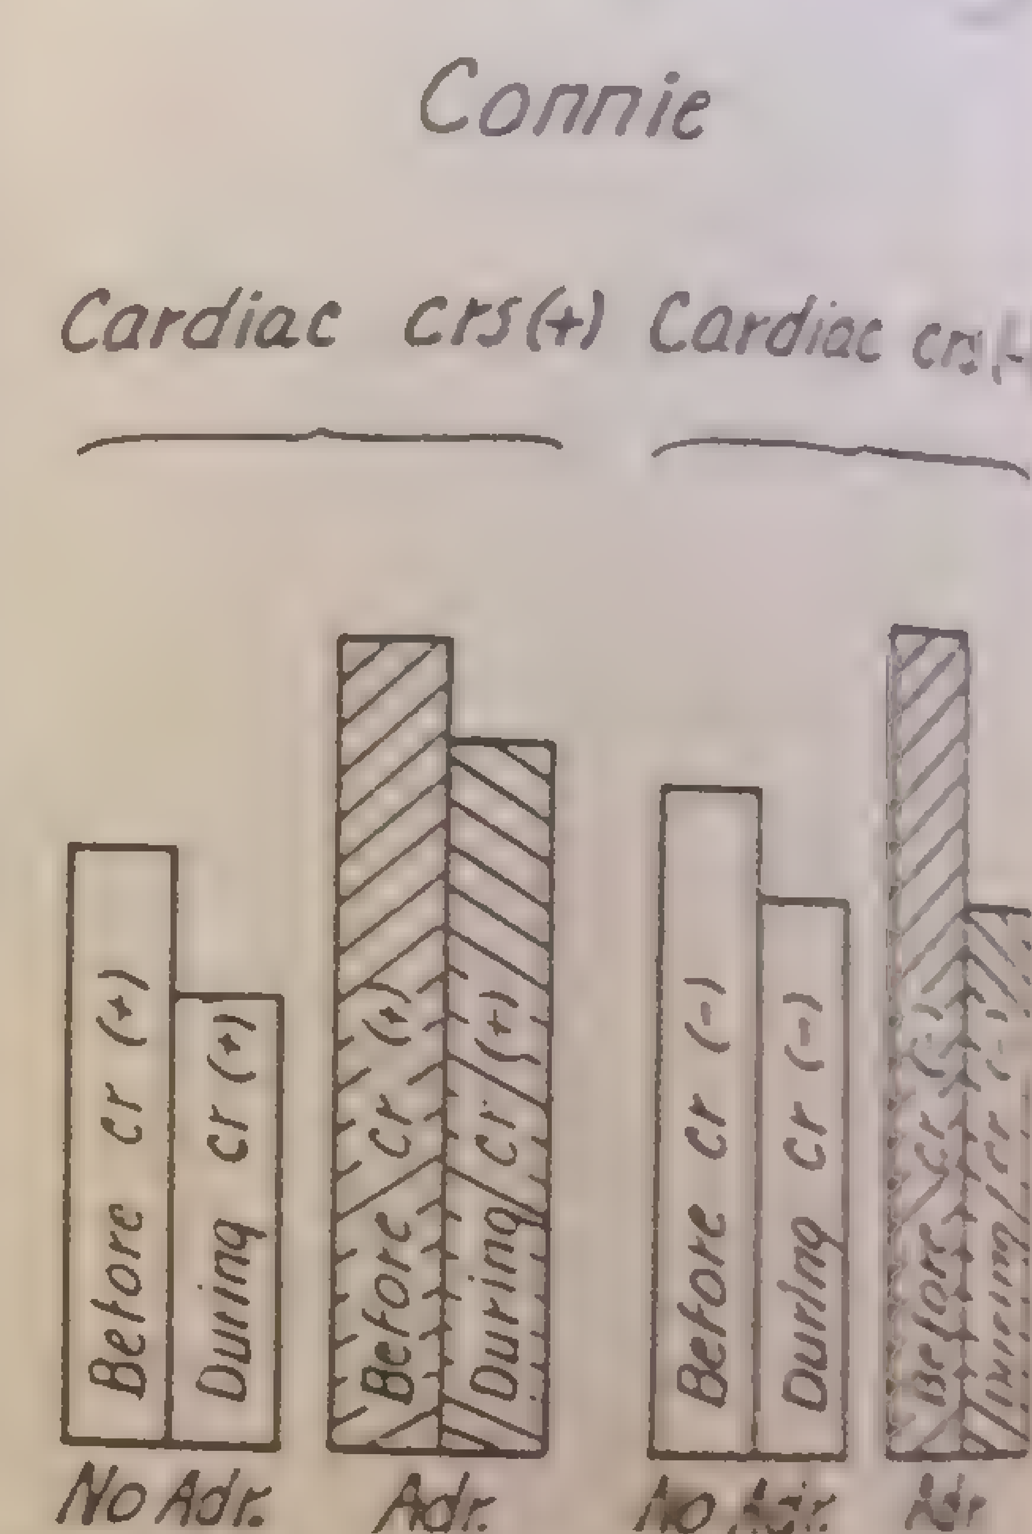


FIG. 19b. Effect of adrenalin on cardiac crs in labile (Nick) and in stable (Connie) [illegible] shows absolute heart rates.

... GASTROINTESTINAL.

In the first experiments with Nick no abnormality in his method of eating was ...d. During experimentation inside the camera before the introduction of the ... differentiation he occasionally refused to eat. As the neurosis progressed,

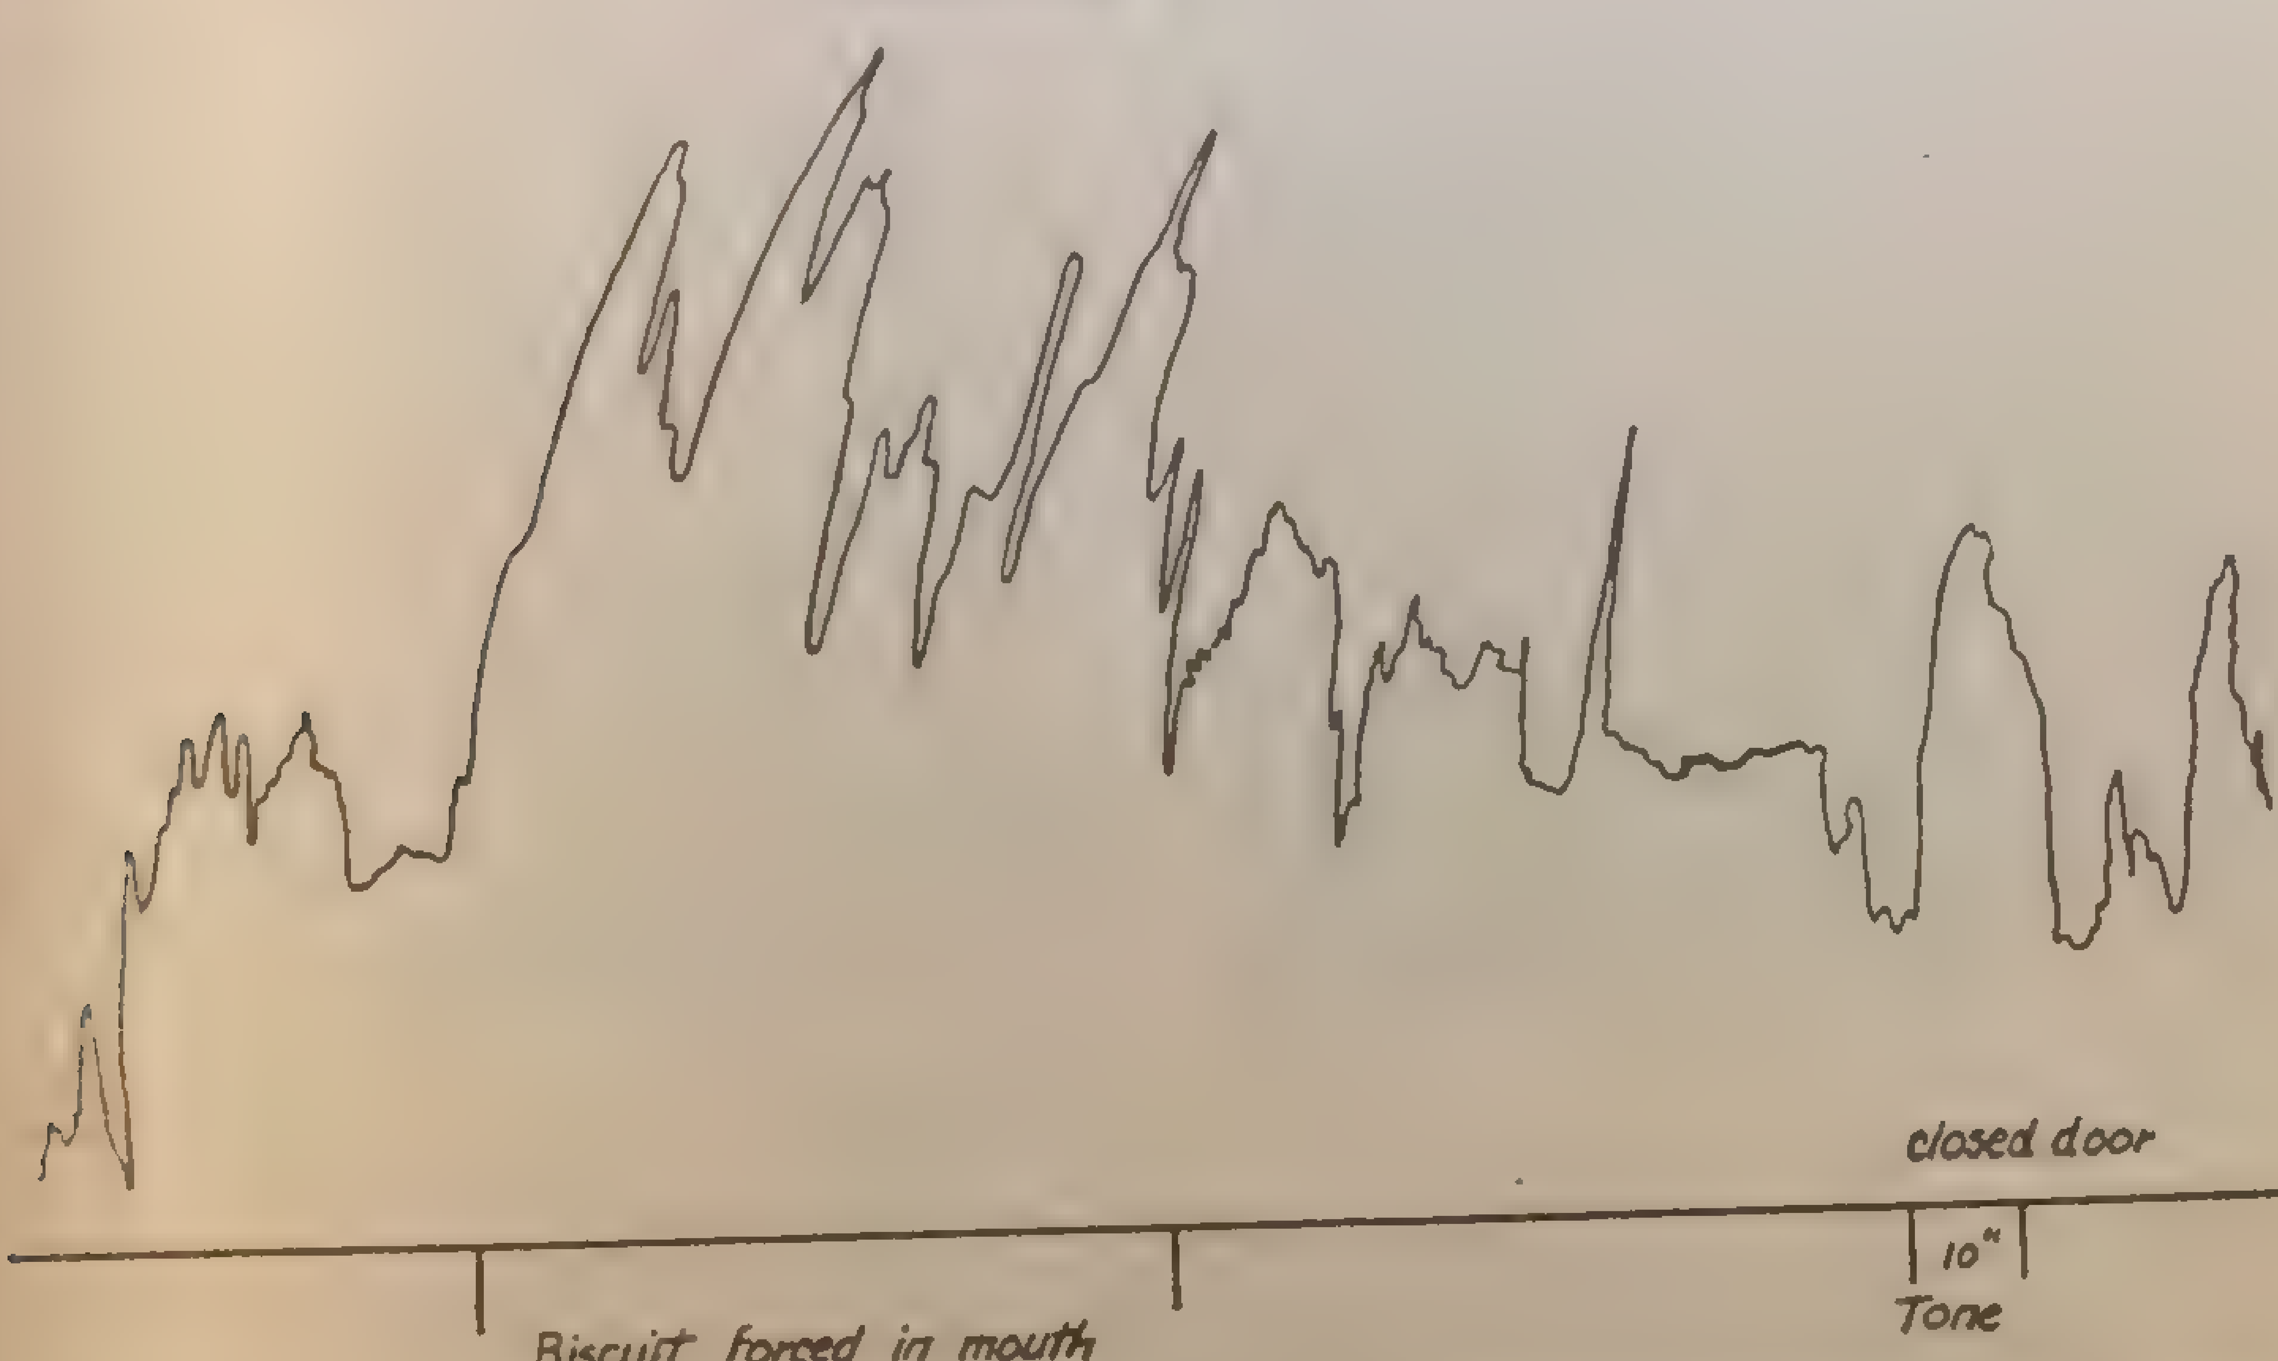

Fig. 2‥. Effect on respiratory response of biscuit forced in mouth. Compare fig. 21 and Table 23.

he consistently refused food inside the camera and often in the antecamera. His appetite was always good and even voracious when removed from the experimental environment—either in his paddock or on the farm. The food excitation became converted during the early part of the conflict to marked defense (or "anxiety"-like) reactions, so that the presentation of food or any of the former food cs would elicit the defense responses (fig. 20). There was usually a definite stage in the routine, such as putting the dog on the stand or attaching the leash, after which he would refuse food, turning his head in the other direction. The various stages of putting the dog in the camera apparently combined to produce complete inhibition of the food excitation. At which stage the dog stopped eating

varied slightly with his condition—sometimes it was simply bringing him [illegible] [illegible], in putting him on the table or attaching the leash, rarely would [illegible] after the salivary disc was applied; the strongest inhibitors were the [illegible] or even any other later elaborated associations, e.g., the light. As the [illegible] was reversed—taking the dog out—the stage at which he again began to [illegible] usually an earlier one (i.e., further removed from the central operation of [illegible]ing the disc) than that at which he refused to eat) suggesting that the inhibition lasted a certain length of time after it was fully established. The negativistic reaction of Nick compared with the positive response of Fritz toward food in the same

Fig. 21. Nick refusing food in camera offered by H.S.

Fig. 22. Fritz accepting food [illegible] H.S.

situation is seen in figures 21 and 22.

When the dog was eating outside the camera, he was immediately inhibited [illegible] would drop the food from his mouth when any of the food csi were given from [illegible] distance, but the effect was weaker the greater his distance from the source of [illegible] signal. Frequently he picked up his food and ran about apparently playing with [illegible] dropping it from his mouth and rolling it around. This act became stere[illegible] lasting for years, and suggested the compulsive behavior of patients. The [illegible] that he received ordinarily in the early cr experiments had an even greater [illegible] when shown to him outside the experimental environment, e.g., on the farm, [illegible] eliciting the "anxiety" and defense responses as well as the sexual reflexes (fig. [illegible] On 17 January, 193[illegible] Nick's aversion to the food appeared in the respirat[illegible] movements when the food was forced into his mouth (fig. 20). Likewise Pet[illegible] refused to eat the food formerly used in the situation of conflict in the camera and was thrown into a panic of barking when he saw it, though he readily accep[illegible]

new type of food (May 1933). Thus there was a specific aversion elaborated to the particular food used in the experiments, as well as a lesser aversion to any kind of food in the camera. The inhibitory effect of the camera was so great that it was difficult to get him to eat highly relished foods such as meat and this even though he had been starved as much as two days previously.[5] The effect of eating this meat in the camera for a period of several months will be discussed under (later).

A peculiar type of defecation with the accompanying neurotic micturition and sexual erections was sometimes observed. This followed a definite pattern—spinning around pivoted on his hindlegs, followed by vigorous pawing and scratching, barking and whining. It was seen particularly in the country during the first few minutes that Nick was taken off the leash while he was excitedly running about, barking, whining and panting.

FIG. 23. Nick on farm refusing food used in laboratory—ovals on ground.

In many of the dogs subjected to stress a fetid odor was noticed in the camera, especially during the period when the conflict was the greatest. Unlike the pollakiuria and the sexual erections, this odor appeared during the acute stress and not later as a trace of conflict. It was observed in many dogs, but particularly in Peter and Nick. Although the source was undetermined, its resemblance to a fecal odor would indicate an intestinal origin.

Peter and Nick not only refused food but developed a marked negativism toward the food. This is seen in the movements—e.g., turning of the head away from the food, occasional retching during the tone—and also in the secretion; the parotid salivary secretion to the natural as well as to the artificial (laboratory) food csi was completely inhibited.

An example of the inhibitory effect of the environment of conflict on the parotid salivary secretion is seen in Table 23 (figs. 21 and 22).

As the csi arising from the proximity of the food (visual, olfactory) are commonly very strong, being old and natural csi, one may reasonably assume that the

[5] Masserman's cats who became neurotic from a blast of air while they were eating refused food as long as 48 hours after starvation (personal communication).

TABLE 23

EFFECT OF CONFLICT ON SECRETION

| COND. STIM. NO PREVIOUS REPETITIONS WITH FOOD | CR (AVERAGE) | UR (AVERAGE) |

above pathological state is reflected in the other secretory digestive gland[illegible] ach, pancreas, liver, intestine.

The interest of Arnold Rich in the gastric secretion in nervous condition[illegible] dogs has provided us with an answer to this hypothetical question sugg[illegible] what I had noted in the parotid secretion. On the initiative of Dr. Rich samp[illegible] of the gastric juice were taken from Nick by a stomach tube (examination[illegible] made in the afternoon 22 hours after the last feeding). Table 24 shows the pre[illegible] ence of a persistent hyperacidity; normal dogs, as known from the work of Pavlov, Babkin, ourselves and others have no free acid in the fasting stomach but [illegible] little alkaline mucous.

TABLE 24

| DATE | FREE HCl | COMBINED HCl | TOTAL ACID |

| 12 Feb. 1942 | 34 | 28 | 62 |
| Median | 34 | 27 | 62 |

Unfortunately earlier experiments were not done on Nick so that we cann[illegible] say definitely whether the hyperacidity is a result of "constitution" or of the induced neurosis. Anomalies of gastrointestinal secretions in nervous patients are well known. The suppression of salivary secretion and the gastric hyperacidity noted by Rich in Nick is comparable to the hyperacidity reported by H. G. Wolf[illegible] (111) during emotional states in patients. The anomalies of the parotid secret[illegible]

[illegible] of the conflict is a clear indication of the effect of environment of [illegible] on digestion; for it was at first normal and then became suppressed as the [illegible] developed (Table 23). On the other hand, the UR salivary secretion, [illegible] secretion to the food after the dog has taken it in his mouth is, like most URs, [illegible]ffected or only slightly decreased by the conflict.

[illegible] anomaly of the gastric secretion, although in the opposite direction of the [illegible] parotid secretion, is an evidence of a widespread disturbance in the diges[illegible] which has extended beyond the limits of the conflict. Although the [illegible]dity has not so far been shown to be dependent upon the environment of [illegible], its presence is of great interest when taken in connection with other ex[illegible] in the autonomic imbalance, e.g., pollakiuria, sexual anomalies. The [illegible] of the blood sugar tolerance curve in Nick is partly the result of [illegible] motility; the autonomic motor system suffers as well as the secretory.

After 8 months of experimentation the food crs were almost compeltely trans[illegible] into defense; indeed the appearance of the particular food biscuit, in the [illegible] or even outside, was often strong enough to initiate marked whining, bark[illegible] and retreating seen as early as 12 October, 1932.

The inhibition of the salivary secretion is an extremely selective one, inhibiting [illegible] the secretion produced in a certain setting. It is possible to elaborate a copious [illegible] to the same tone that was connected with the conflict when this tone [illegible] subsequently used as a signal for *defense* (acid into the mouth) instead of [illegible]. Hence it is evident that the inhibition is not absolute for the tone but [illegible] the tone used in a special way.[a]

The strong potential action of the tone (though no longer a stimulus for food) [illegible] by the fact that it can be used as the basis for elaborating other specific [illegible] reflexes. See for example, the ease with which *Light-associated-with-Tone* [illegible] a stimulus for the anxiety-like reactions (Ch. VI, section 8).

### [illegible]. Respiration

No abnormalities were noted in Nick's respiration before the elaboration of crs, [illegible]ugh he was previously brought down several times into the experimental [illegible]m. Later four types of respiratory disorder developed.

[a] This fact might be taken by many as an argument against the "rigid mechanistic" attitude of Pavlov [illegible] plastic "dynamic psychobiology" based upon "meaning," as suggested by Masser[illegible]). New terms which stimulate new thinking and experimentation, and discovery of new facts [illegible]. "Meaning" as a principle hardly explains any more than "conditional reflex." It has the [illegible] for scientific use of being capable of various interpretations and incapable of experimental [illegible] the meaning may exist in the mind of the interpreter rather than in the subject. If a strict definition [illegible]le or state which inclines toward or prepares for a certain line of action is given to it, as [illegible] by Whitehorn, the concept becomes more widely applicable. In spite of the novelty and attrac[illegible] words let us not forget that "a rose by any other name would smell as sweet" and "that [illegible] sound and fury" (Goethe).

Before describing the abnormal breathing it is well to point out the chan[ge] respiration that ordinarily occurs to the food csi and to eating. Normal [dogs] show some increase in respiratory movements to csi but the normal chan[ges are] slight compared to Nick's. Also the greatest change in respiration in the [normal] comes with the UR—the act of eating—but with Nick there is a much [greater] change to the csi after they have ceased to be food signals. Thus compar[e the]

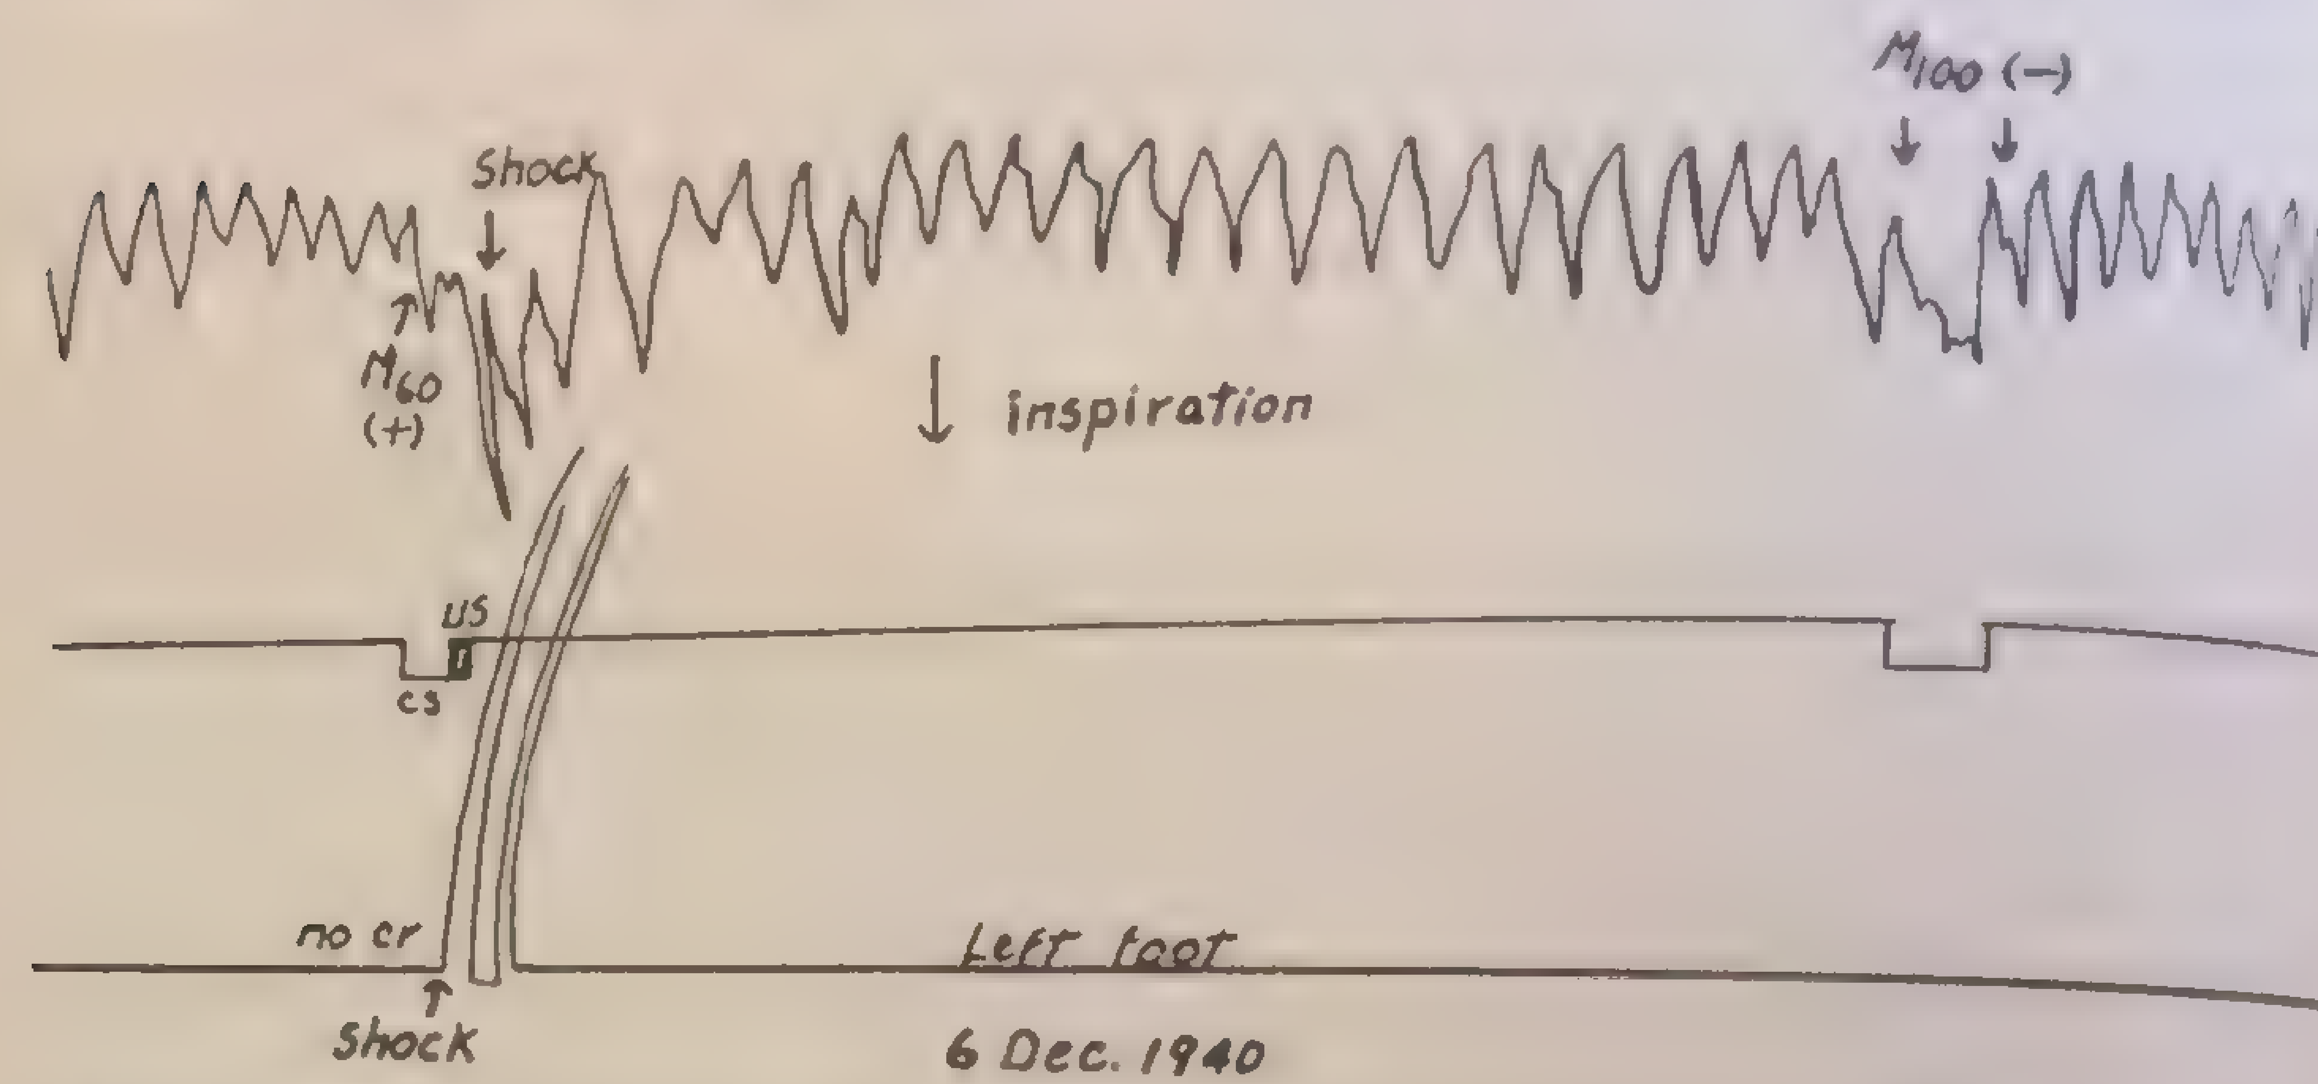

FIG. 24. Regular respiration in stable dog (C) even before differentiation (dog receives shock

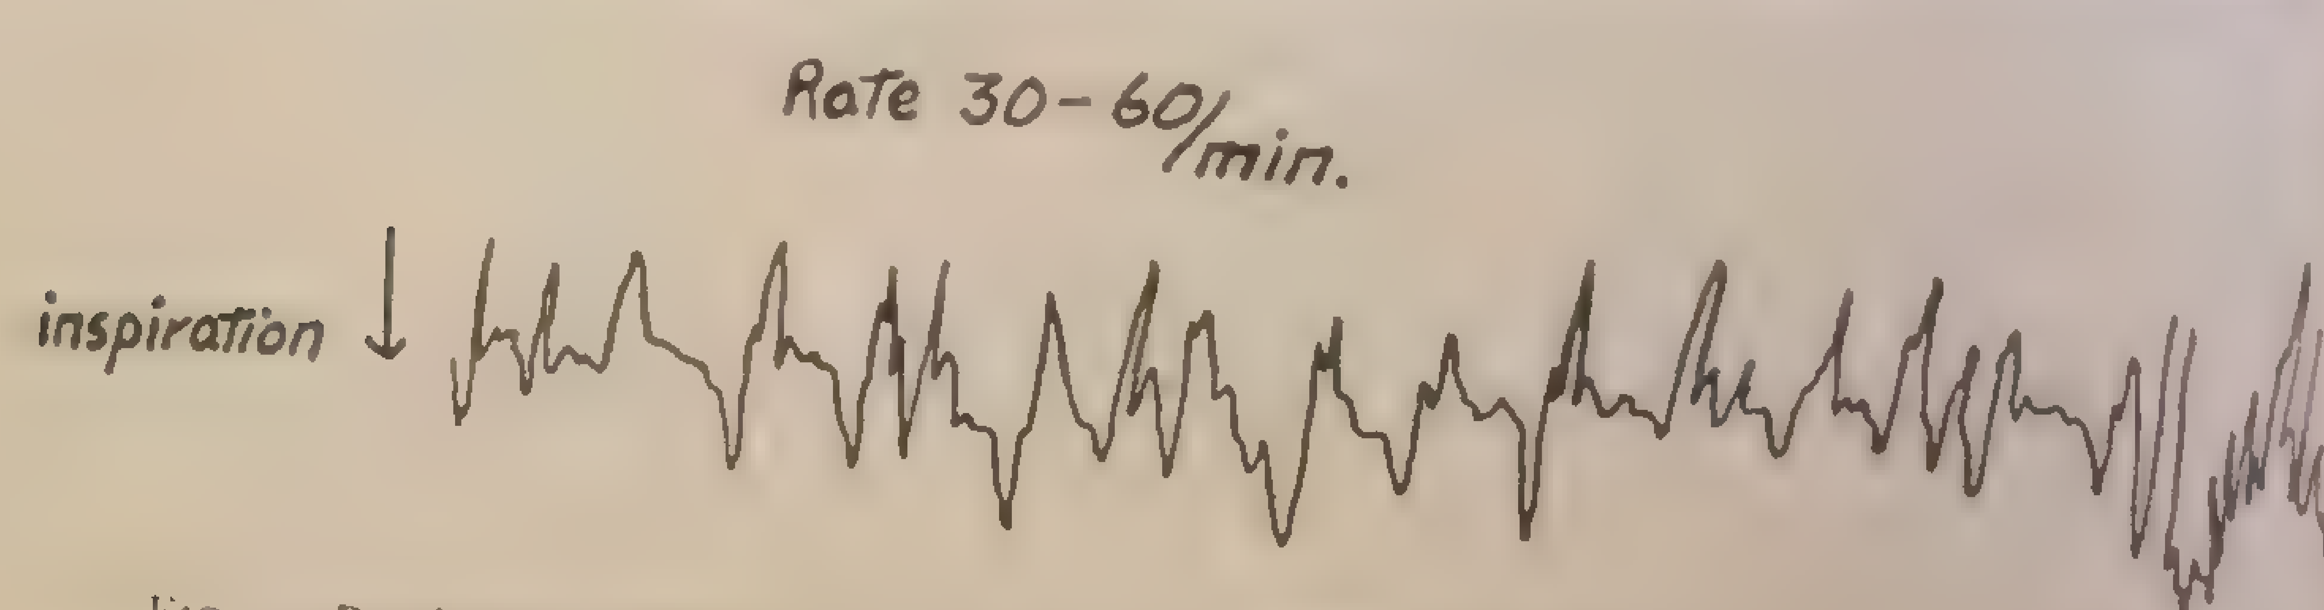

FIG. 25. Respiration of Nick 27 February, 1941, showing disturbed character. Cf. with fig. 24

respiration of normal dogs (fig. 24) with that of Nick (fig. 25) even when he [is] outside of the camera.

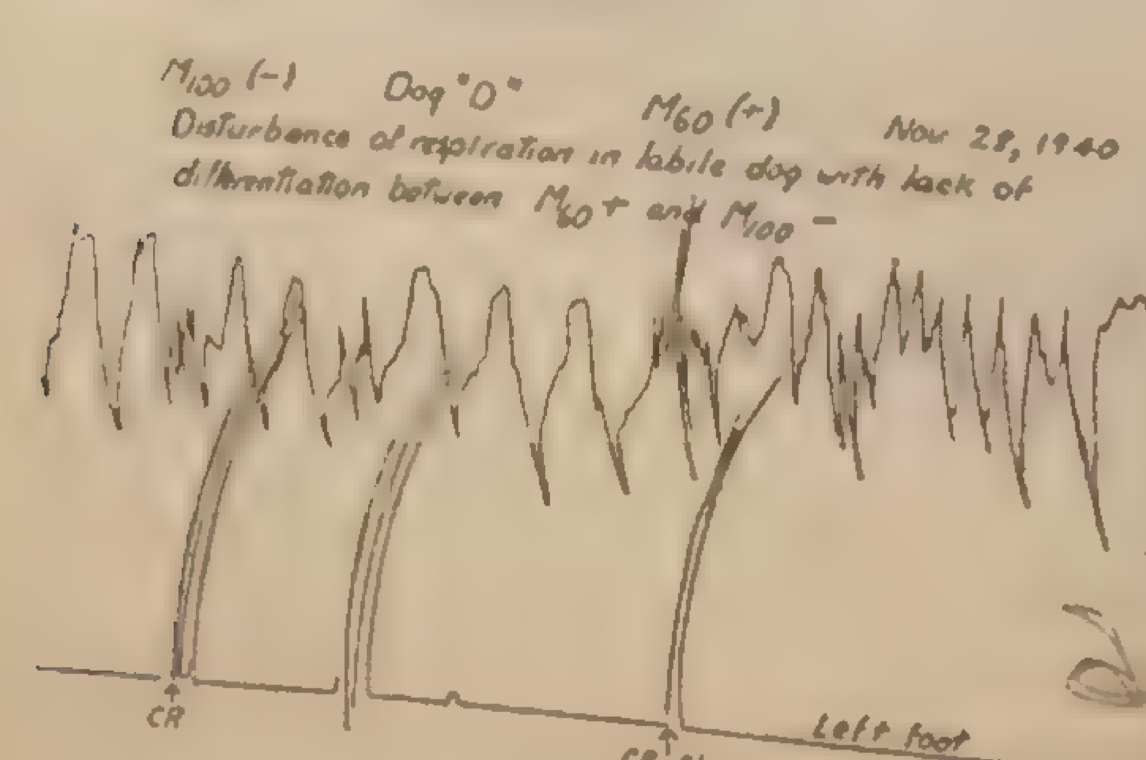

FIG. 26.

Nick's respiration is much more sim[i]lar to that of an unstable dog during the cs for a painful stimulus (electric). Com[pare] example of Nick's response [to] former food csi) (fig. 13) with that [of] Dog D (to painful csi) (fig. 26).

The first type of pathological respira[tion] was rapid breathing (panting) which came in the early part of the conflict and has lasted until the present, reaching

... respiratory cycles per minute. The second was a definite stereotyped pattern of breathing resembling asthma superficially, and seen whenever he was aroused but particularly in the experimental environment. The third was a type of respiration elicited specifically by any of the anxiety-producing stimuli used in the camera. The fourth type of respiration was a quieter one noted in the emotional state accompanying petting and often in the end stage of normal sexual excitation (figs. 33 and 34).

The rapid breathing was first noted in February 1932 in the camera. It appeared to be ordinary rapid panting occurring almost any time the dog was brought into the camera, or even when he was running about in the antecamera, or being brought down to the camera. Inspiration and expiration were smooth and regular and of nearly equal duration without the plateau effect seen in the third type.

The rapidity of 150-250 was maintained for as long as 10 or 15 minutes with only occasional and short remissions to a normal rate of 15 per minute (see fig. 25, 27 February, 1941). When anyone approached Nick in his paddock rapid breathing also occurred and was noted by ordinary counting to be 90 to 180 on 8 March, 1941 (counted by F.B.A., who had never worked with Nick, standing outside Nick's door). Hence it could not be chiefly the result of the attachment of the pneumograph or other apparatus (fig. 27).

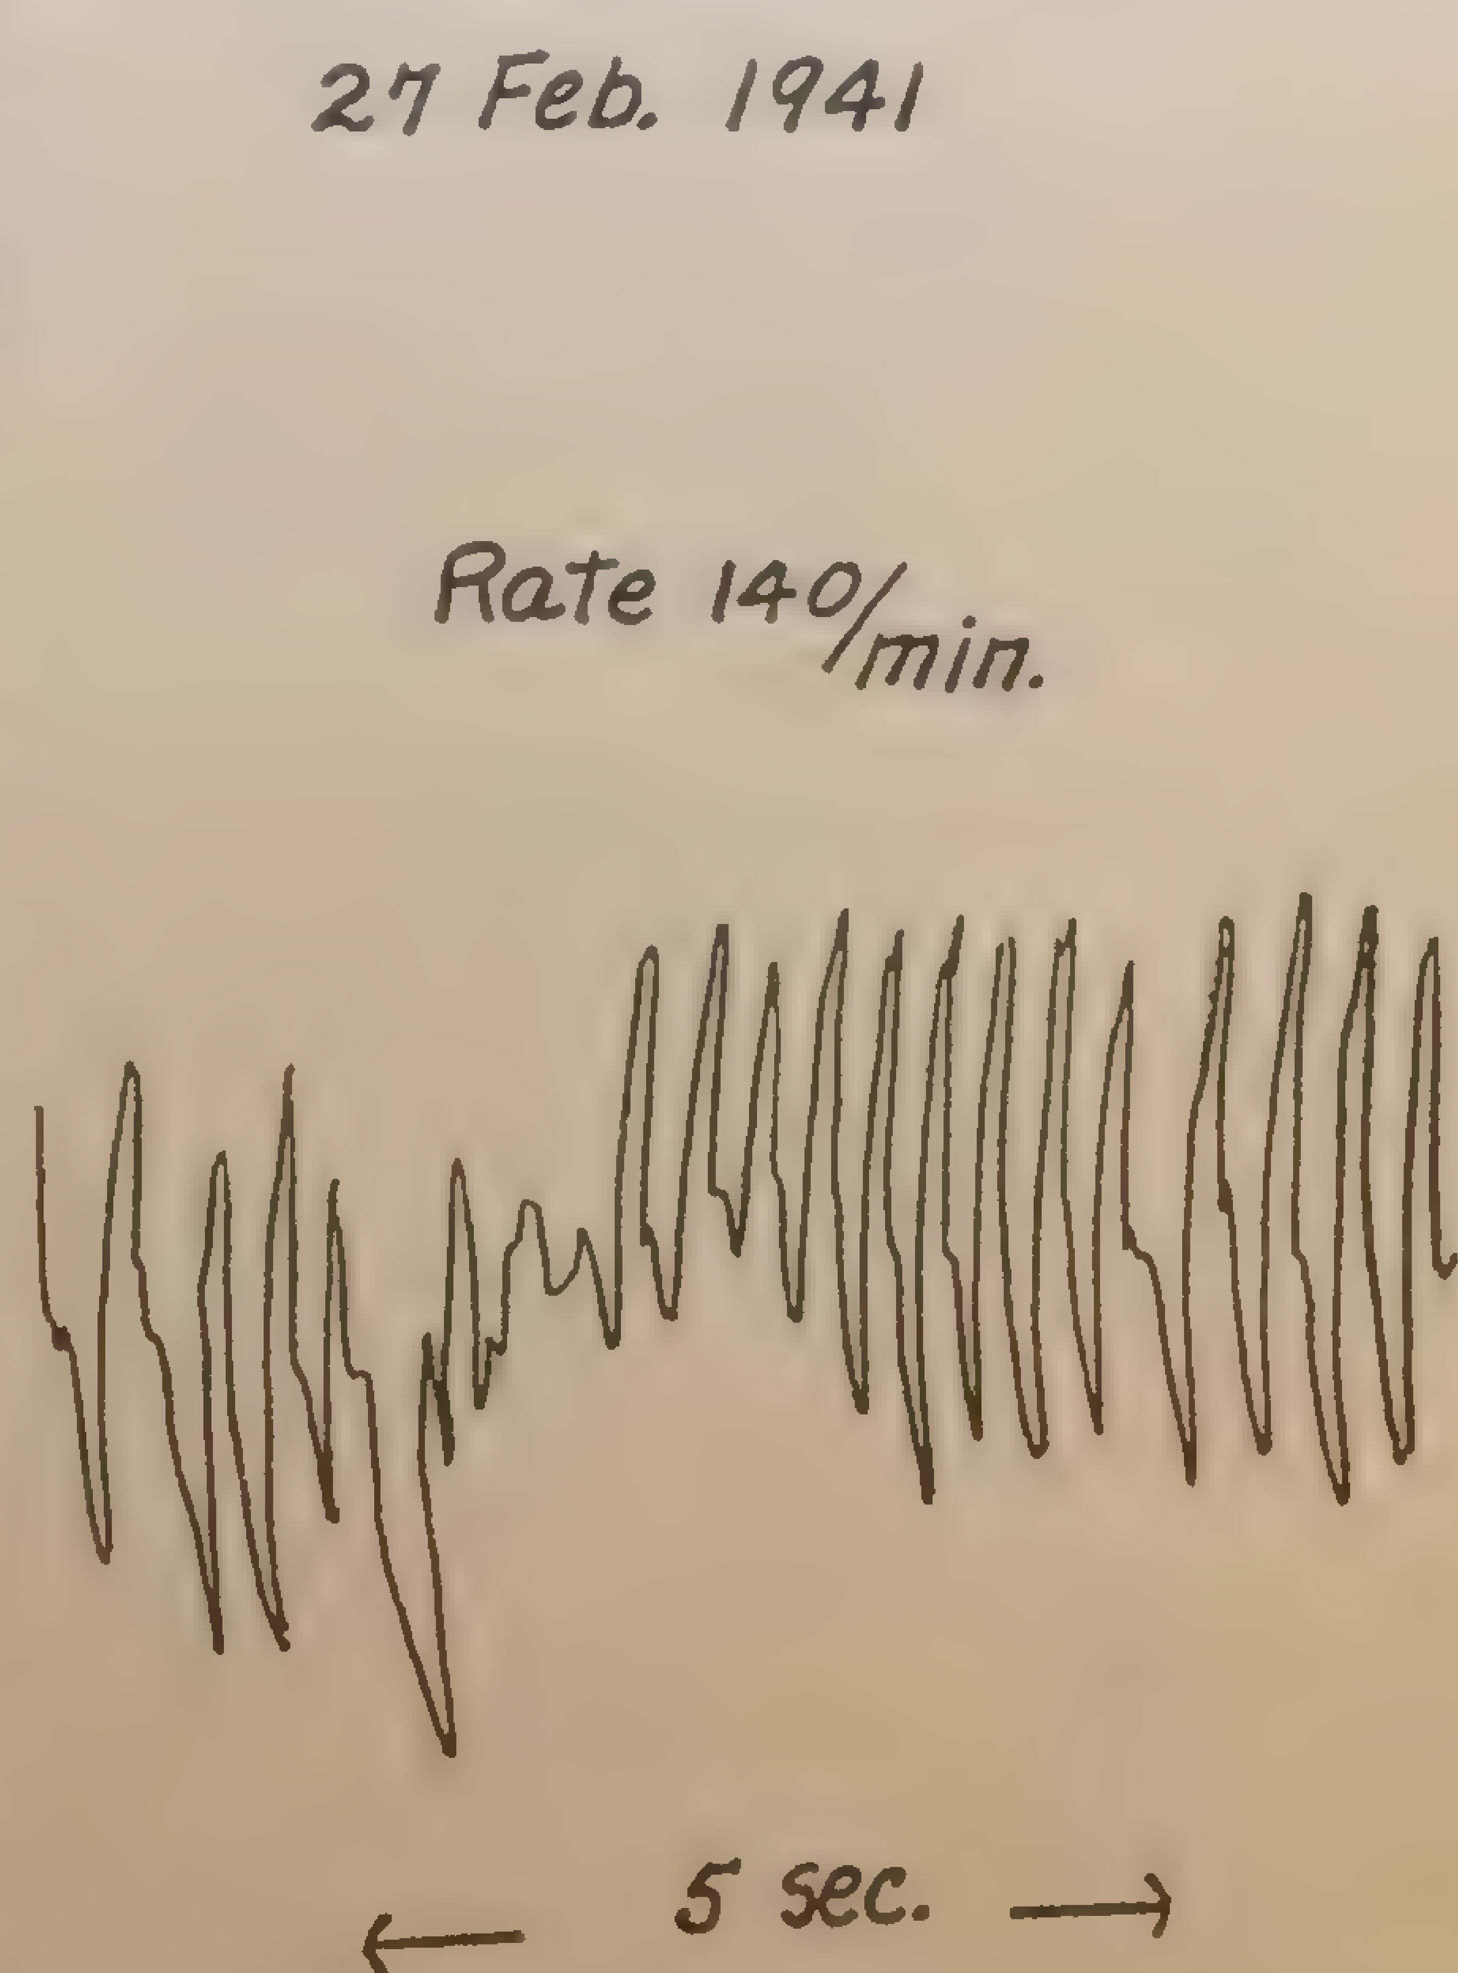

FIG. 27. Rapid (first type) respiration (140/min.) in Nick while in C.

The rapidity of the respiration was very striking (and probably near the maximum possible for dogs) and compares with upper limits in physiological states. Thus a few minutes after metrazol convulsion, a rate of 150-200 was seen (experiments of Victor Rosen and Gantt [97]); Bard (4) has noted in thermal panting a maximum rate of 400, and Kellogg (105) has reported 500 to 600 during panting but only for a few minutes without remissions, while in Nick the rate was 150-250 for nearly 10 minutes.

The second type of respiration was the definite stereotyped asthma like pattern dating from 1935—several years after the original conflict—appearing whenever Nick was brought into the camera, increasing with severity as he approached the camera, but never seen in the paddock until someone who had worked with him came near. However, it was sometimes present in other situations when he became excited. This breathing was very noisy, raucous in character, audible for several hundred feet, in appearance like a slow, labored breathing, rate about 10 per minute, inspiration and expiration about equal. Figs. 11 and 12 show this type of breathing, occurring in fig. 11 after the 3rd, 4th, and 5th csi and in fig. 12 just after the 1st cs.

Examination of Nick's lungs (Dr. Murray Fisher, 1938) revealed no evidence of bronchial spasm, i.e., no musical rales as in true human asthma.

A *third type* of breathing was that which developed about 1934 to the specific stimuli used in the camera, also remaining as a stereotyped pattern from 1934 to 1941. It consisted in a single smooth deep inspiration followed by a slow, jerky, sometimes staircase expiration. The inspiration lasted 6 to 10 seconds, and the expiration about twice as long but it was marked by the step-like character. There was usually a long plateau broken by shallow breathing (figs. 11 and 28). This breathing was seen not only with the tone involved in the conflict, but to a variety of related stimuli, such as to the metronome, to a bubbling sound, or to almost any auditory stimulus used in the camera, even to the dropping of the food or to the entrance of a person who had worked with Nick (figs. 29, 30, 31).

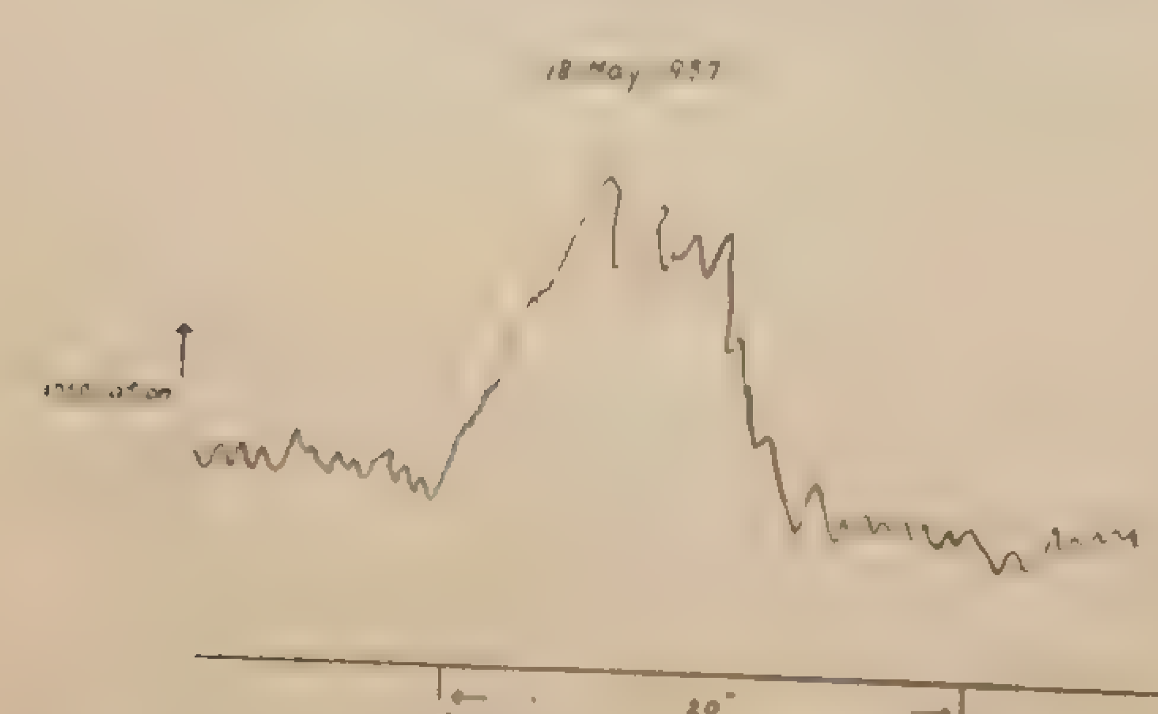

FIG. 28. Third type respiratory response in Nick to Tone.

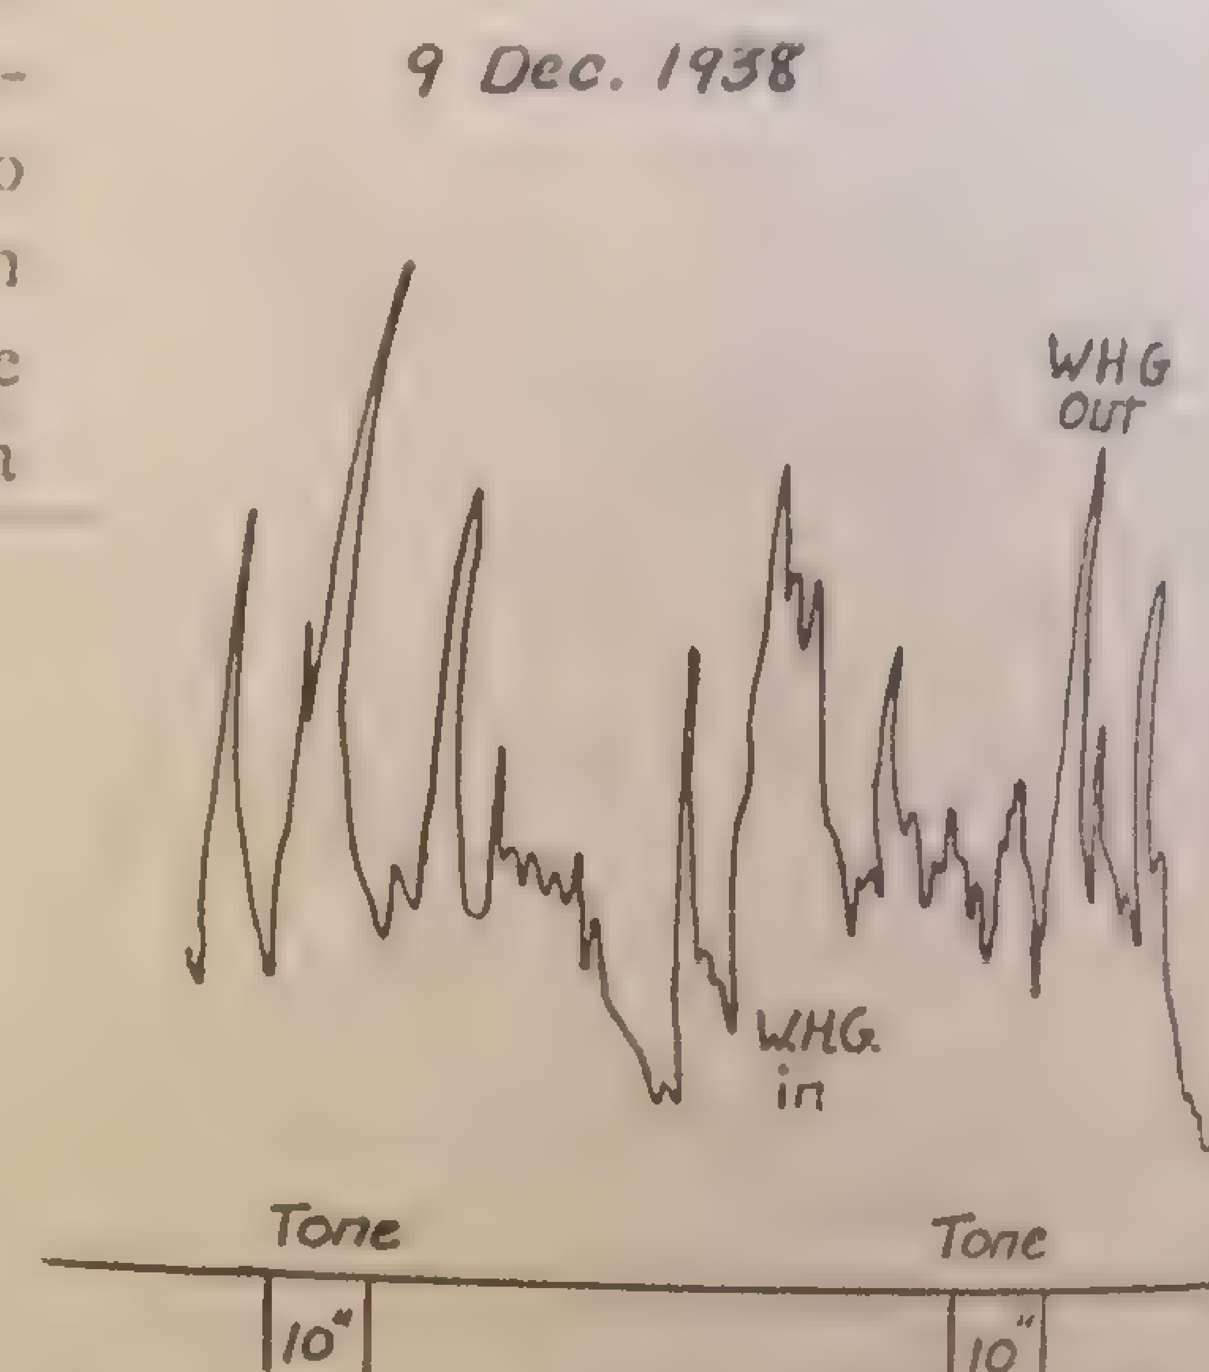

FIG. 29. Showing effect of entrance and exit of person on Nick's respiration.

This third pattern of respiration was more specifically related to the conflict than to an auditory stimulus per se. Thus in 1937 I saw that it could be developed from a previously neutral stimulus; a flashing light (L60) first used in 1937

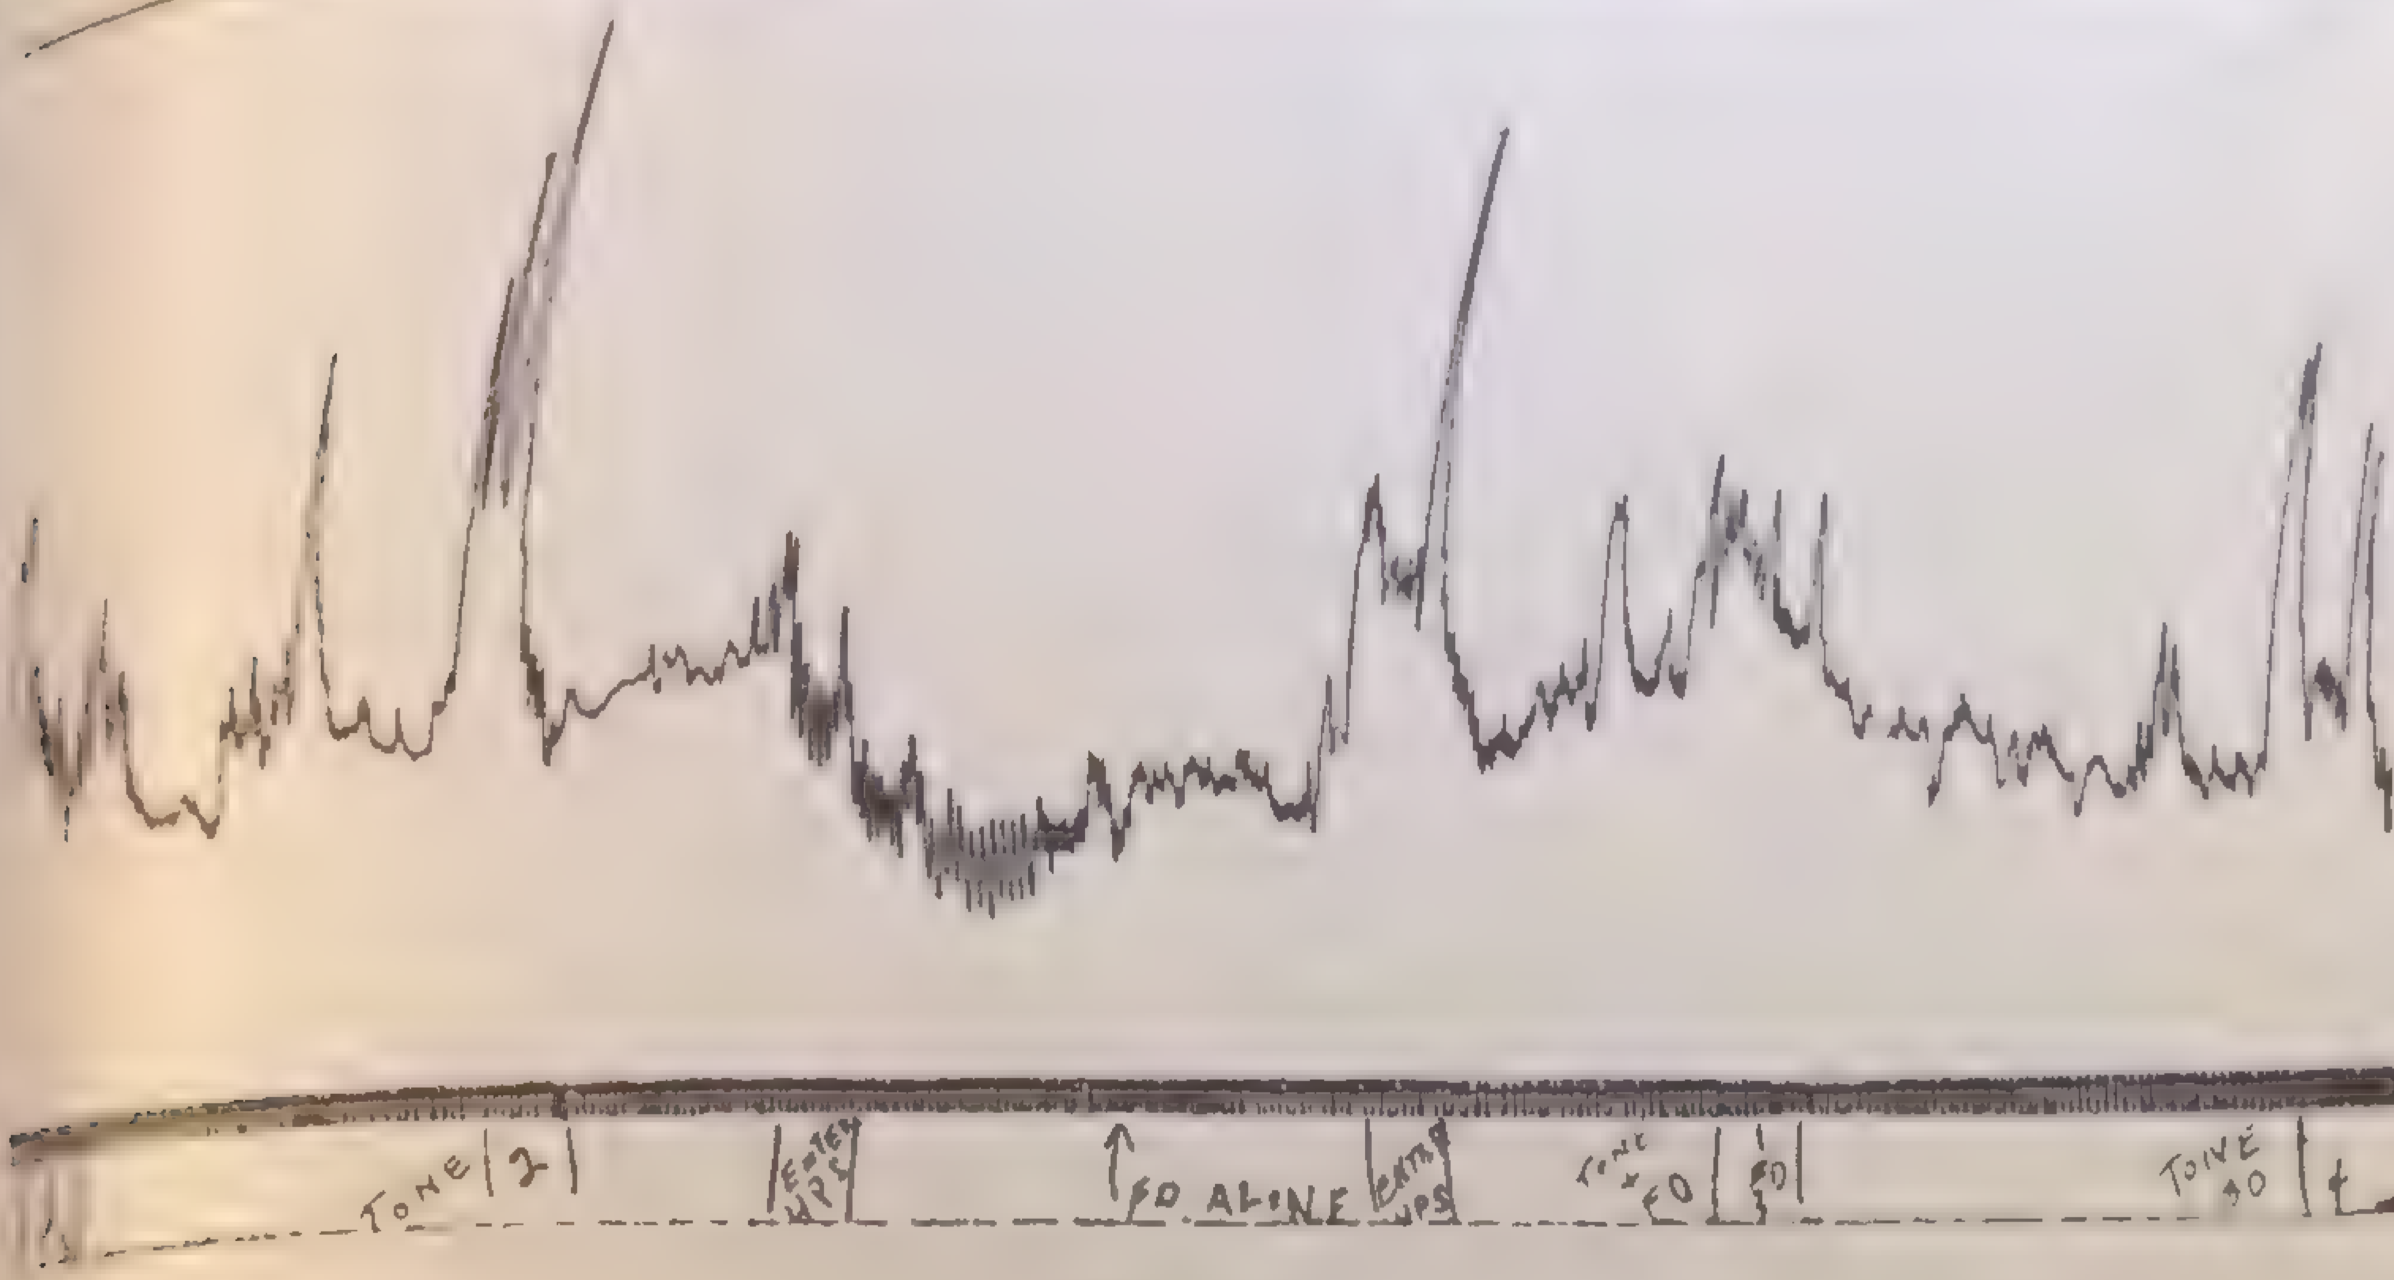

FIG. 30.

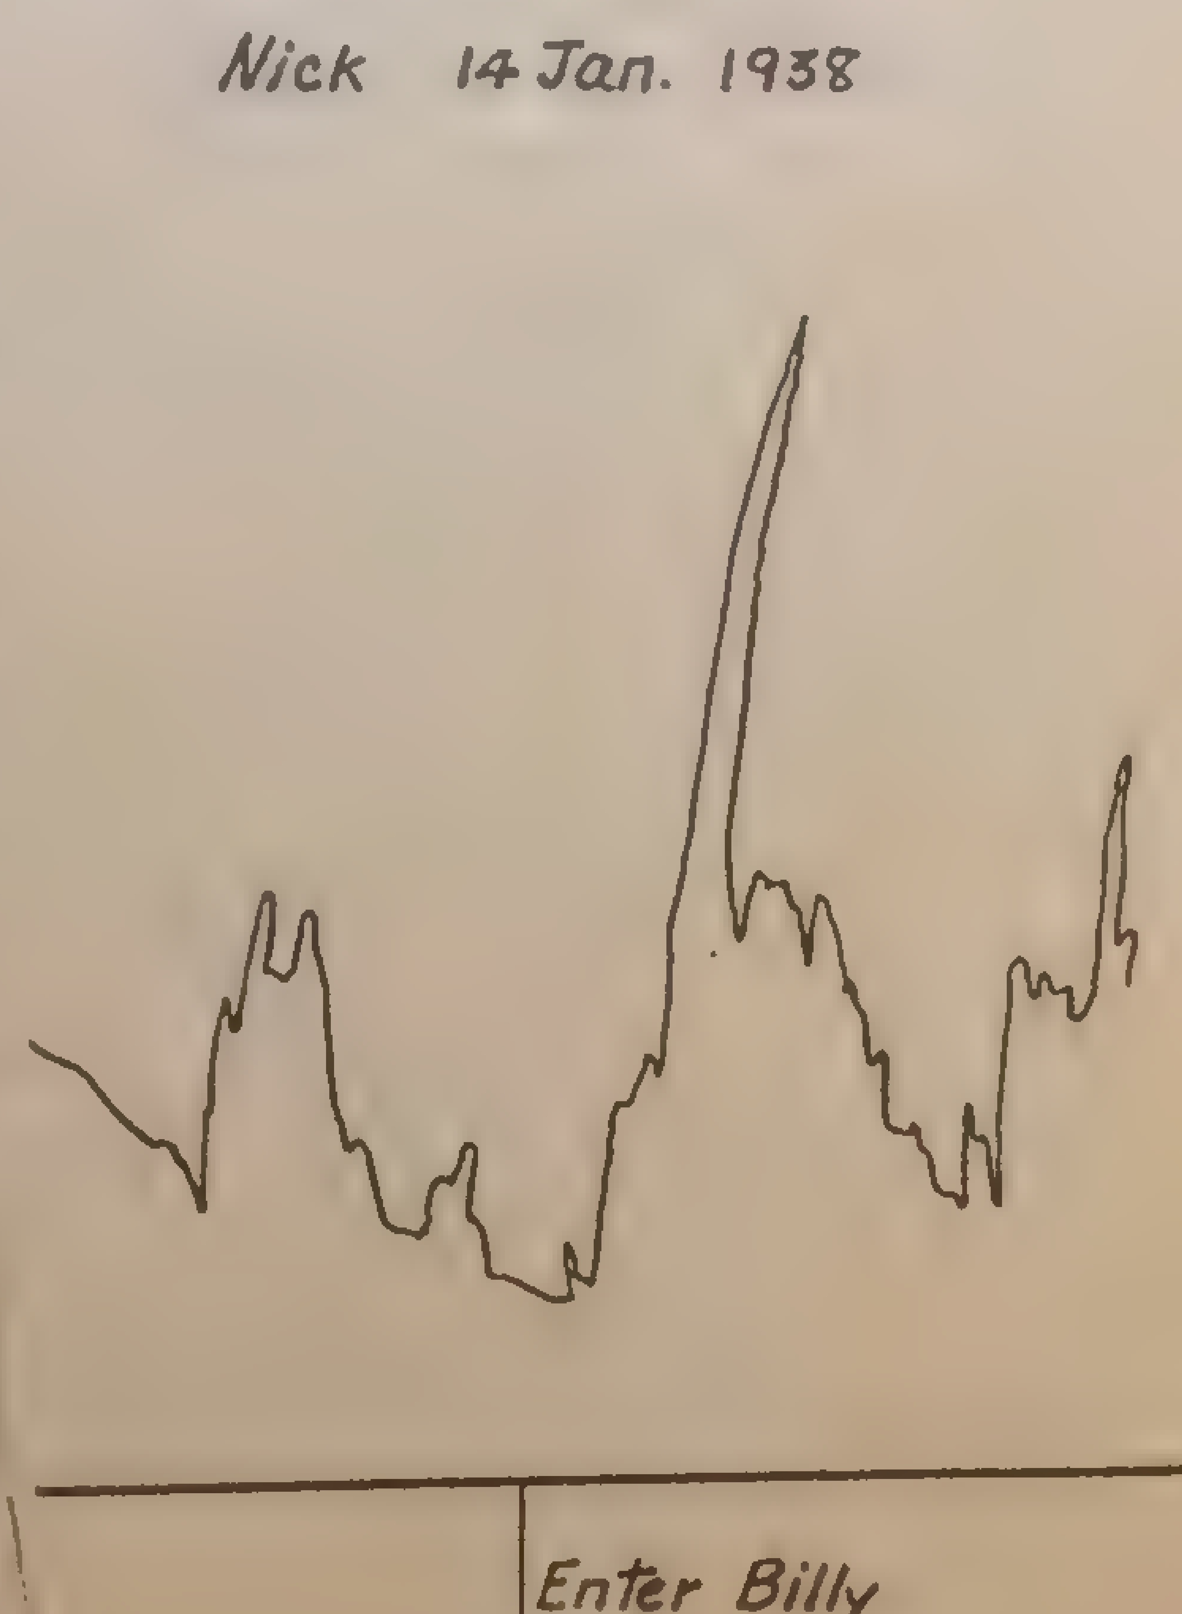

FIG. 31. Respiratory change produced by extraneous stimulus (in C) in Nick.

of the camera was without effect on Nick, but after combining it with the tone for 15 trials (giving the light for 5 seconds before the tone and 3 seconds after the beginning of the tone) it elicited the same type of breathing as the tone itself, with the difference that the abnormal breathing did not begin immediately to the light as it had to the tone, but only after the light had acted 3 or 4 seconds, and the reaction to the light was less stable than it was to the auditory stimuli (fig. [illegible]).

In comparing with other types of disturbance the pattern of Nick's disturbance in respiration to a specific auditory stimulus, it is more similar to the type of respiration seen in the response to a painful stimulus, and is also seen in patients having anxiety symptoms (*48*). As mentioned above, to each auditory stimulus given in or near the camera, or even to the dropping of the food, Nick gave a quick deep inspiration which was held for some seconds and then expelled in short, expiratory, staircase-like stages. This is similar to the usual type of respiration seen when the animal actually receives a painful faradic shock, as has been

described by the author (45), and by Kellogg and Walker ([illegible]). Al[illegible] Kellogg found this pattern of respiration peculiar to the US (shock), I have [illegible] frequently seen it as a respiratory cr in especially labile dogs besides Nick. [illegible] for example the respiration in dog D on 28 November, 1940 (fig. [illegible]).

Fig. 12 shows in contrast the second and third types of respiration, the [illegible] occurring in characteristic form to the third T cs, and the third type also [illegible] third, fourth, fifth T csi. The first type is not so marked here as in fig. [illegible]

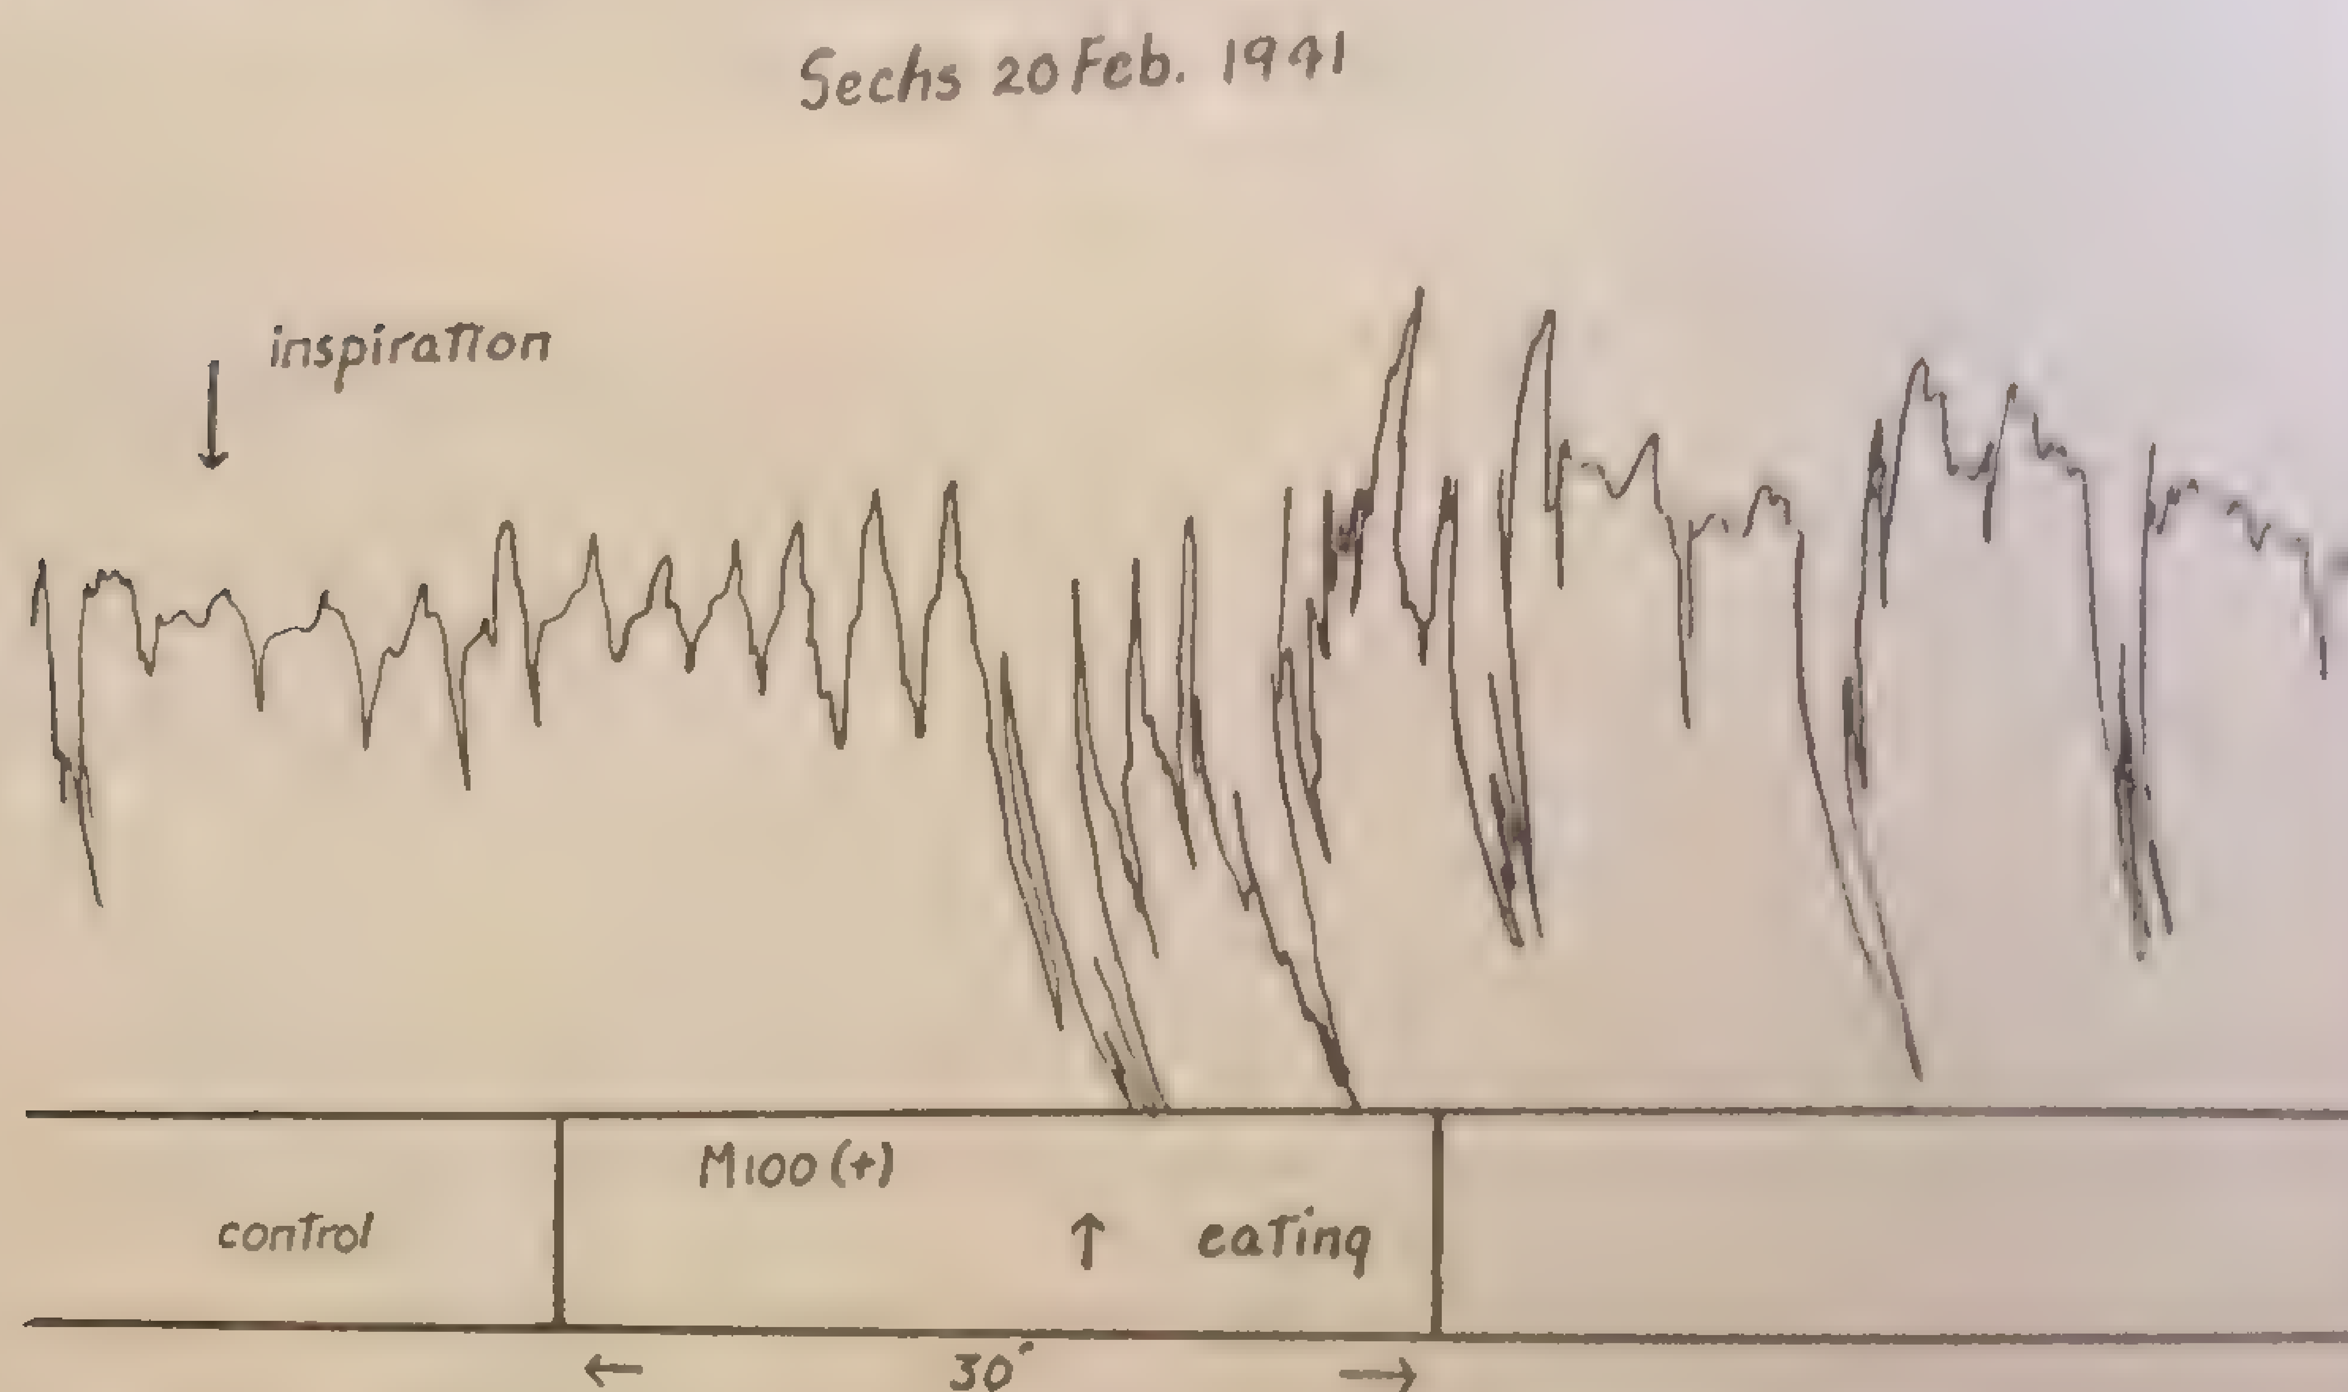

FIG. 32. Respiration in normal dog in C during cr and during UR (eating). Only slight [illegible] in rate to M100 compared with Nick.

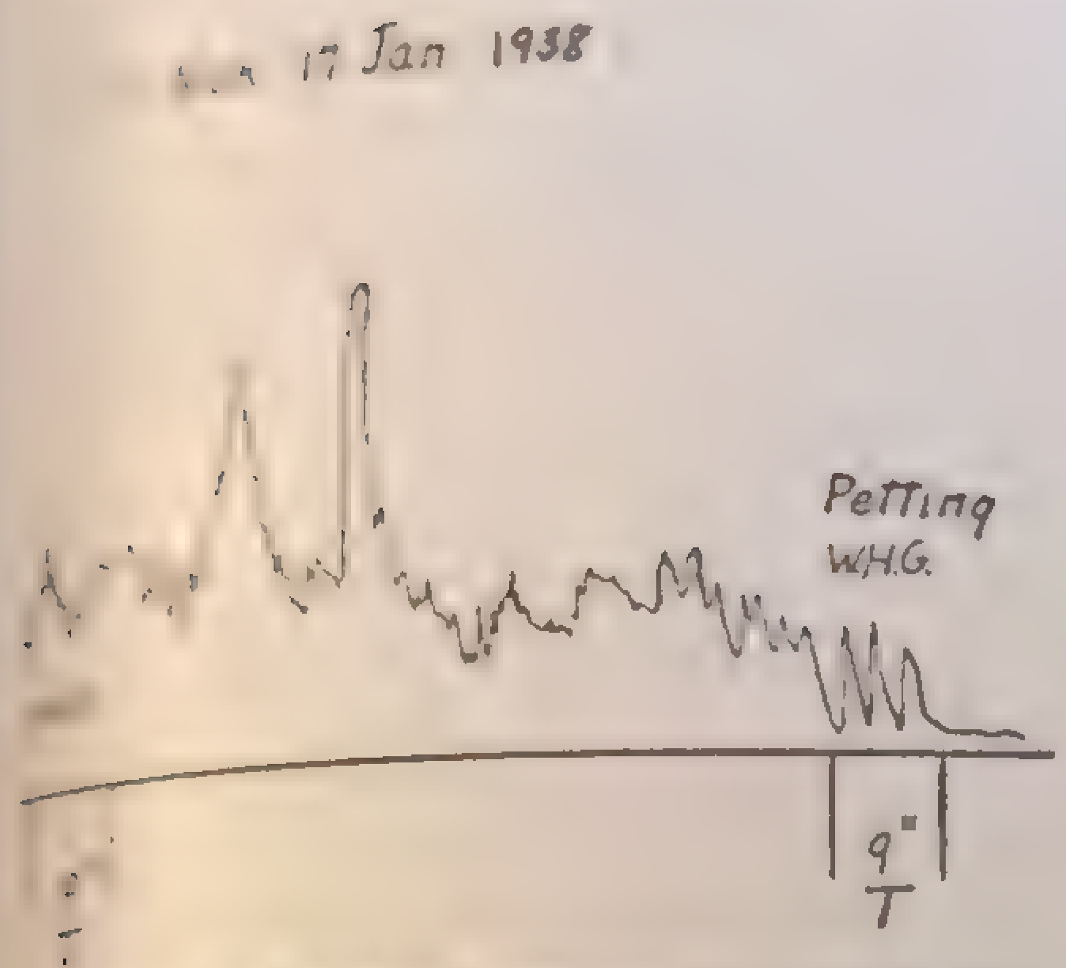
It is important to note that while Nick's pattern of respiration to the former food csi is similar to the respiration to a painful stimulus, it is different from the respiration to a food stimulus in a normal dog. The excitation of the fo[illegible] duces increased rapidity and amplitude of respiration, but not the prolonged [illegible] like expiration. Compare for example the respiration in the dog, Sechs (fi[illegible]). There is no pathological breathing caused by M100, though the rate [illegible] accelerated, and the act of eating, though accompanied by irregular respi[illegible] does not have the pattern of Nick's stereotyped respiratory reaction.

The effect of the neurotic environment on Nick's respiration can be seen [illegible] return to the normal after a period of rest in the country. See, for example, [illegible] for 6 October, 1937 (fig. 10).

[illegible] in respiratory rate with anxiety neuroses, hysteria a[illegible] [illegible] hypochondriasis, reactive depression, compulsion neurosis and schizo[illegible]

[illegible] the abnormal types of respiration seen in Nick, there was a fourth [illegible] pattern which occurred both when he was being petted (fig. 33) [illegible] stage of sexual excitation (fig. 34). This was strikingly similar in



[illegible] Fourth type respiration in Nick dur[illegible] anxiety type breath[illegible], regular, deep respiration, [illegible]. Compare with figs. 28 and 34.

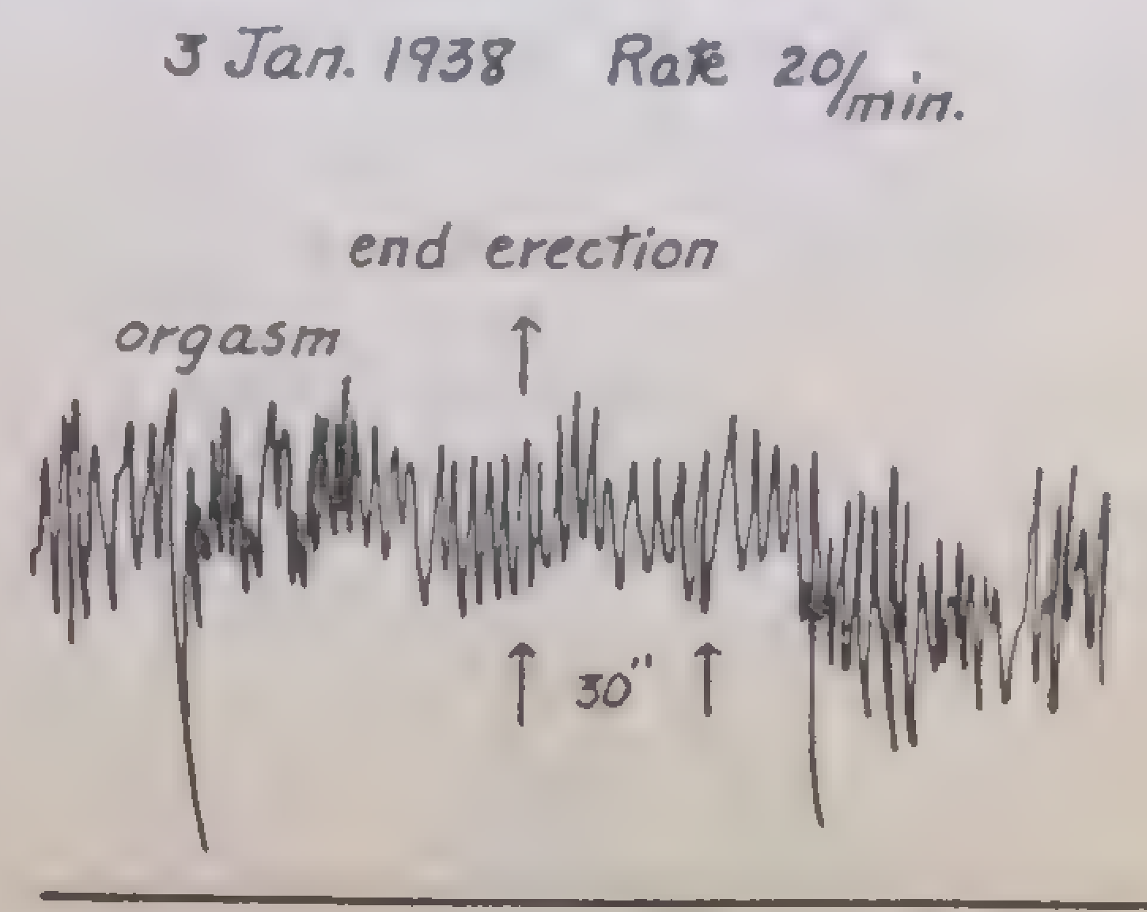


FIG. 34. Respiration in Nick during and after sexual excitation (with orgasm). Slower, regular, deep.

[illegible] emotional states, the pattern consisting in slow, fairly deep and regular [illegible] both as regards amplitude and frequency. However, the respiration [illegible] the pathological sexual erections was of an entirely different type, [illegible] out (similar to the respiration in figs. 27 and 28)—evidence that one [illegible] same reaction may at one time be normal, at another time pathological. [illegible] effect of non-specific stimuli used with Nick in the camera such as opening [illegible] and the presence of another dog Billy is similar to the pathologic respira[illegible] type 3, as seen in the record for 14 January, 1938 (fig. 13).

[illegible] French, Alexander (*28*), Dunbar (*19*), et al. have pointed out (psycho[illegible]) how human asthma originates on a basis of conflict. Although the present [illegible] in Nick were not strictly of the same type as clinical asthma, it is possible [illegible] the close relation of the abnormal breathing to the stimuli of conflict, as [illegible] the whole environment in which they have occurred.

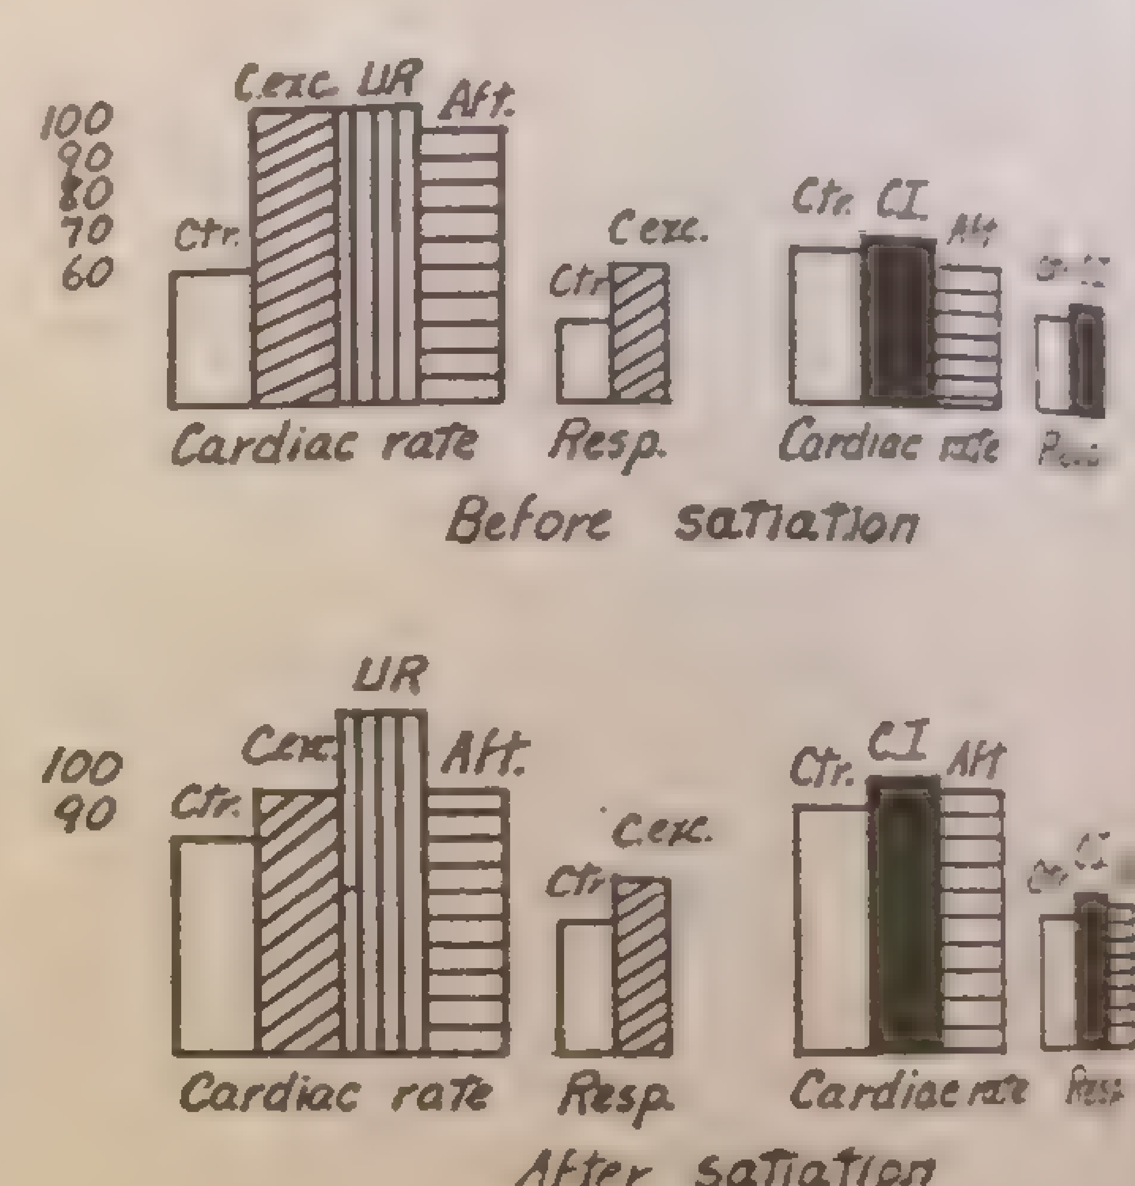
[illegible] respiratory movements recorded in these experiments are of course not a [illegible] index of the basal metabolism or of the gaseous exchange.

## [illegible] CHANGES

[illegible] discussing the pathological fluctuations in heart rate, it is necessary to [illegible] mind what are the normal relations during the cr experiment. Hoffmann [illegible] have shown that there is a specific change in the heart rate accom-

panying both the cr to food and the cr to a painful stimulus. It [illegible] (generally and also from exact experiments) that the heart rate [illegible] various kinds of exercise (Gasser [50], Miles [65]) and with emot[illegible] ment (Cannon [12], Dill [16], Liddell [72], Whitehorn [108]). O[illegible] gations revealed that there was, independently of any overt m[illegible] a specific and quantitative change in the heart rate to the cs and to the [illegible] of stimulus (food or shock) represented by the cs, and also a specific [illegible] the inhibitory stimulus. The heart rate (cr) accompanying both the cr [illegible] tion and a cr pain excitation is usually an acceleration, though in [illegible] retardation.[8] In our normal dogs the change in heart rate during the [illegible] period of the food cs varied from 7% to 30% with the excitatory [illegible] half as much with the inhibitory cs (fig. 35). The cardiac cr is moreover [illegible] more delicate as well as a more stable response than either the secretory, the respiratory or the motor cr, and closely related to the state of the animal (fig. 36). Thus in a dog (Peik) that had

Note



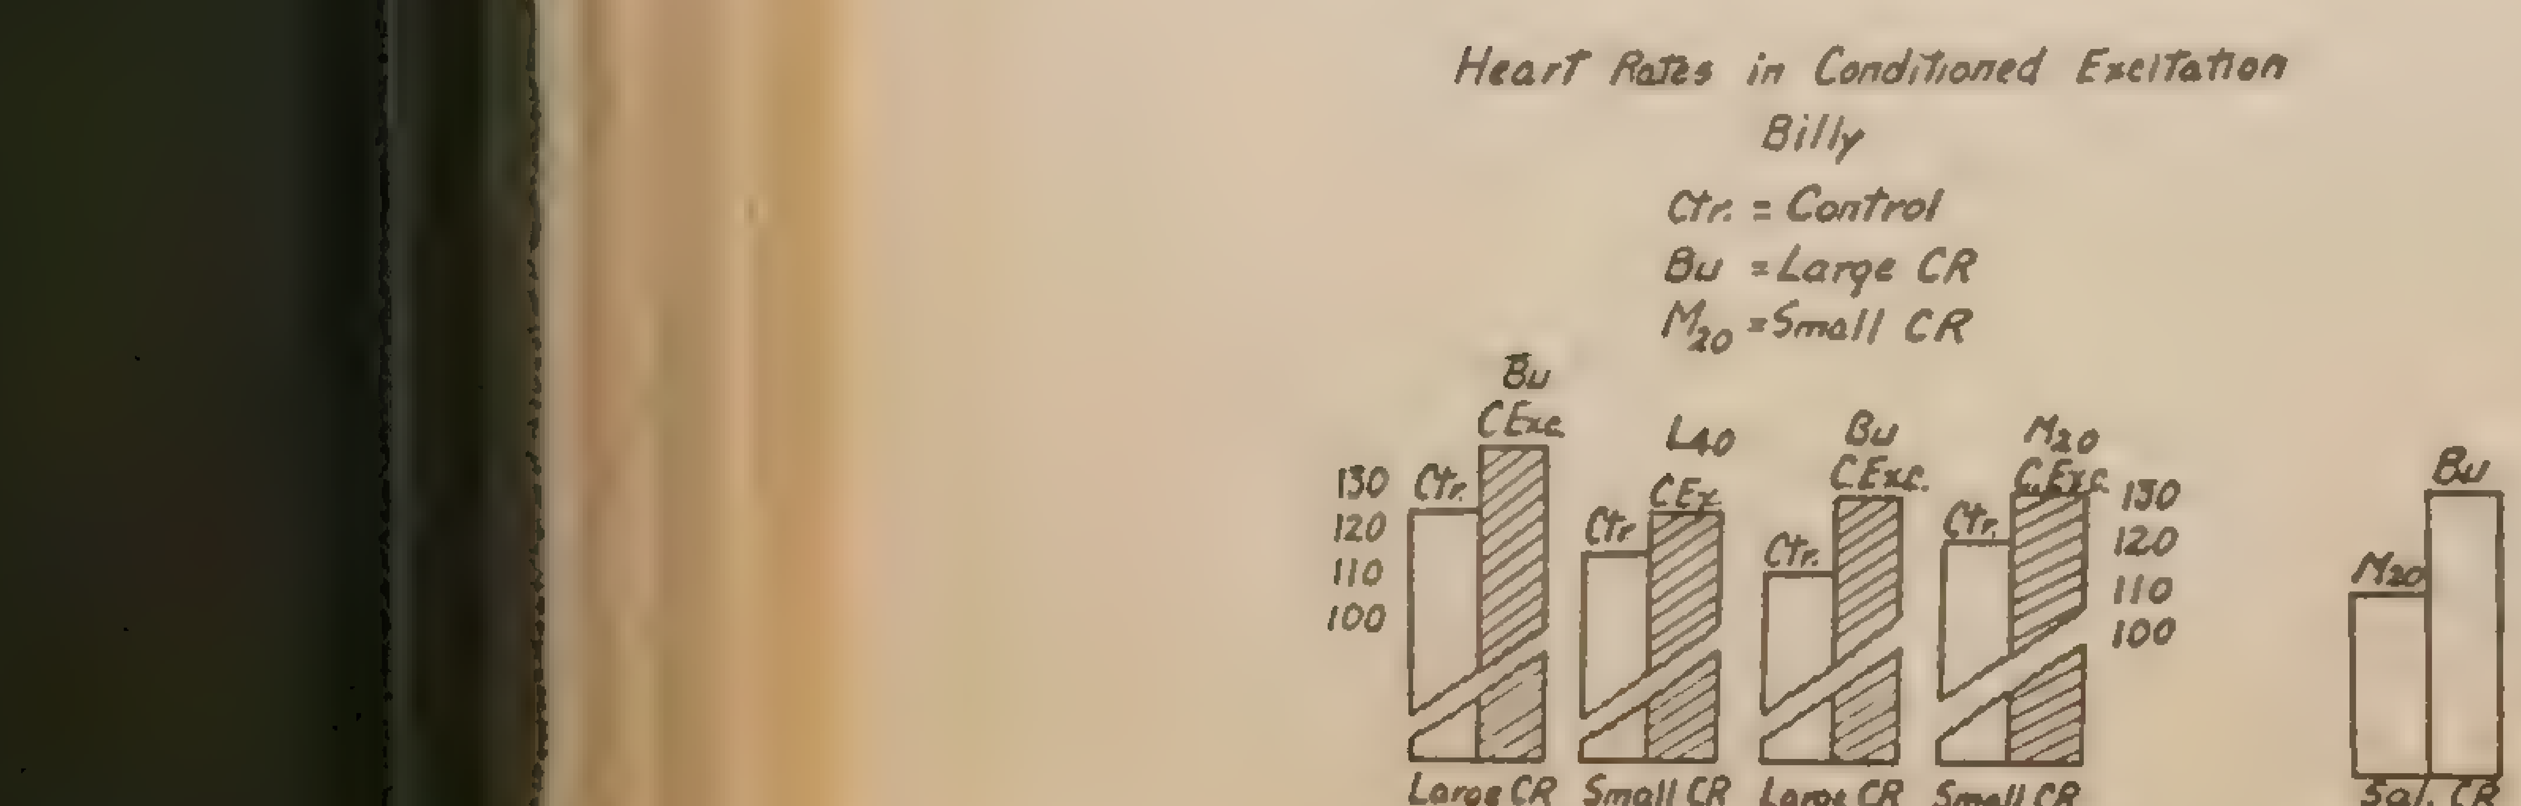


FIG. 35.

FIG. 36. Cardiac and respiratory [illegible] tion and in inhibition (d[illegible] animal). Note the smaller crs [illegible] nals after satiation.

been used for a year in the laboratory there was both retention and differen[illegible] of the cardiac crs, though the motor as well as the secretory were exting[illegible] after this interval (experiments of M. Tunick).

In the elaboration of a new differentiation in the crs, one begins to see a de-parture from the normal increase in heart rate which has been established to [illegible] positive cs, suggesting that an underlying emotional disturbance is involved [illegible] in simple differentiation, whether the US be food or pain. This fluctuation in the heart rate is much more marked in the labile dogs than in the stable ones. Figur[illegible]

[8] We are unable to confirm the statement of Bechterev that the heart is slow with pleasurable [illegible] tions and speeded with the sudden, startling and unpleasant. Although we found that petting of the [illegible] in the pathological milieu slowed his respiration and probably the heart, our results agree more clos[illegible] with those of Whitehorn on patients (108).

...the changes in heart rate produced by the difficult differentiation in both ...d labile dogs.

The disturbance of the heart rate is usually parallel to the disturbance ...tor and secretory crs (see Chapter IV, section 2, Kompa and Peik). ...certain dogs the cardiac cr may reveal a disturbance in behavior ...ither the motor or the ...s. For example, in a ... parturition, which is ... reflected in a loss of ... between the negative crs, ...d no disturbance in the ..., although it did in the ...nding cardiac crs (see ... and fig. 38). If the dif-...tion is not too difficult ... dog too labile, the upset ... a permanent one, and the ... rate drops as soon as the ...ntiation is accomplished, ...rmal except when the ... positive and negative ... given.

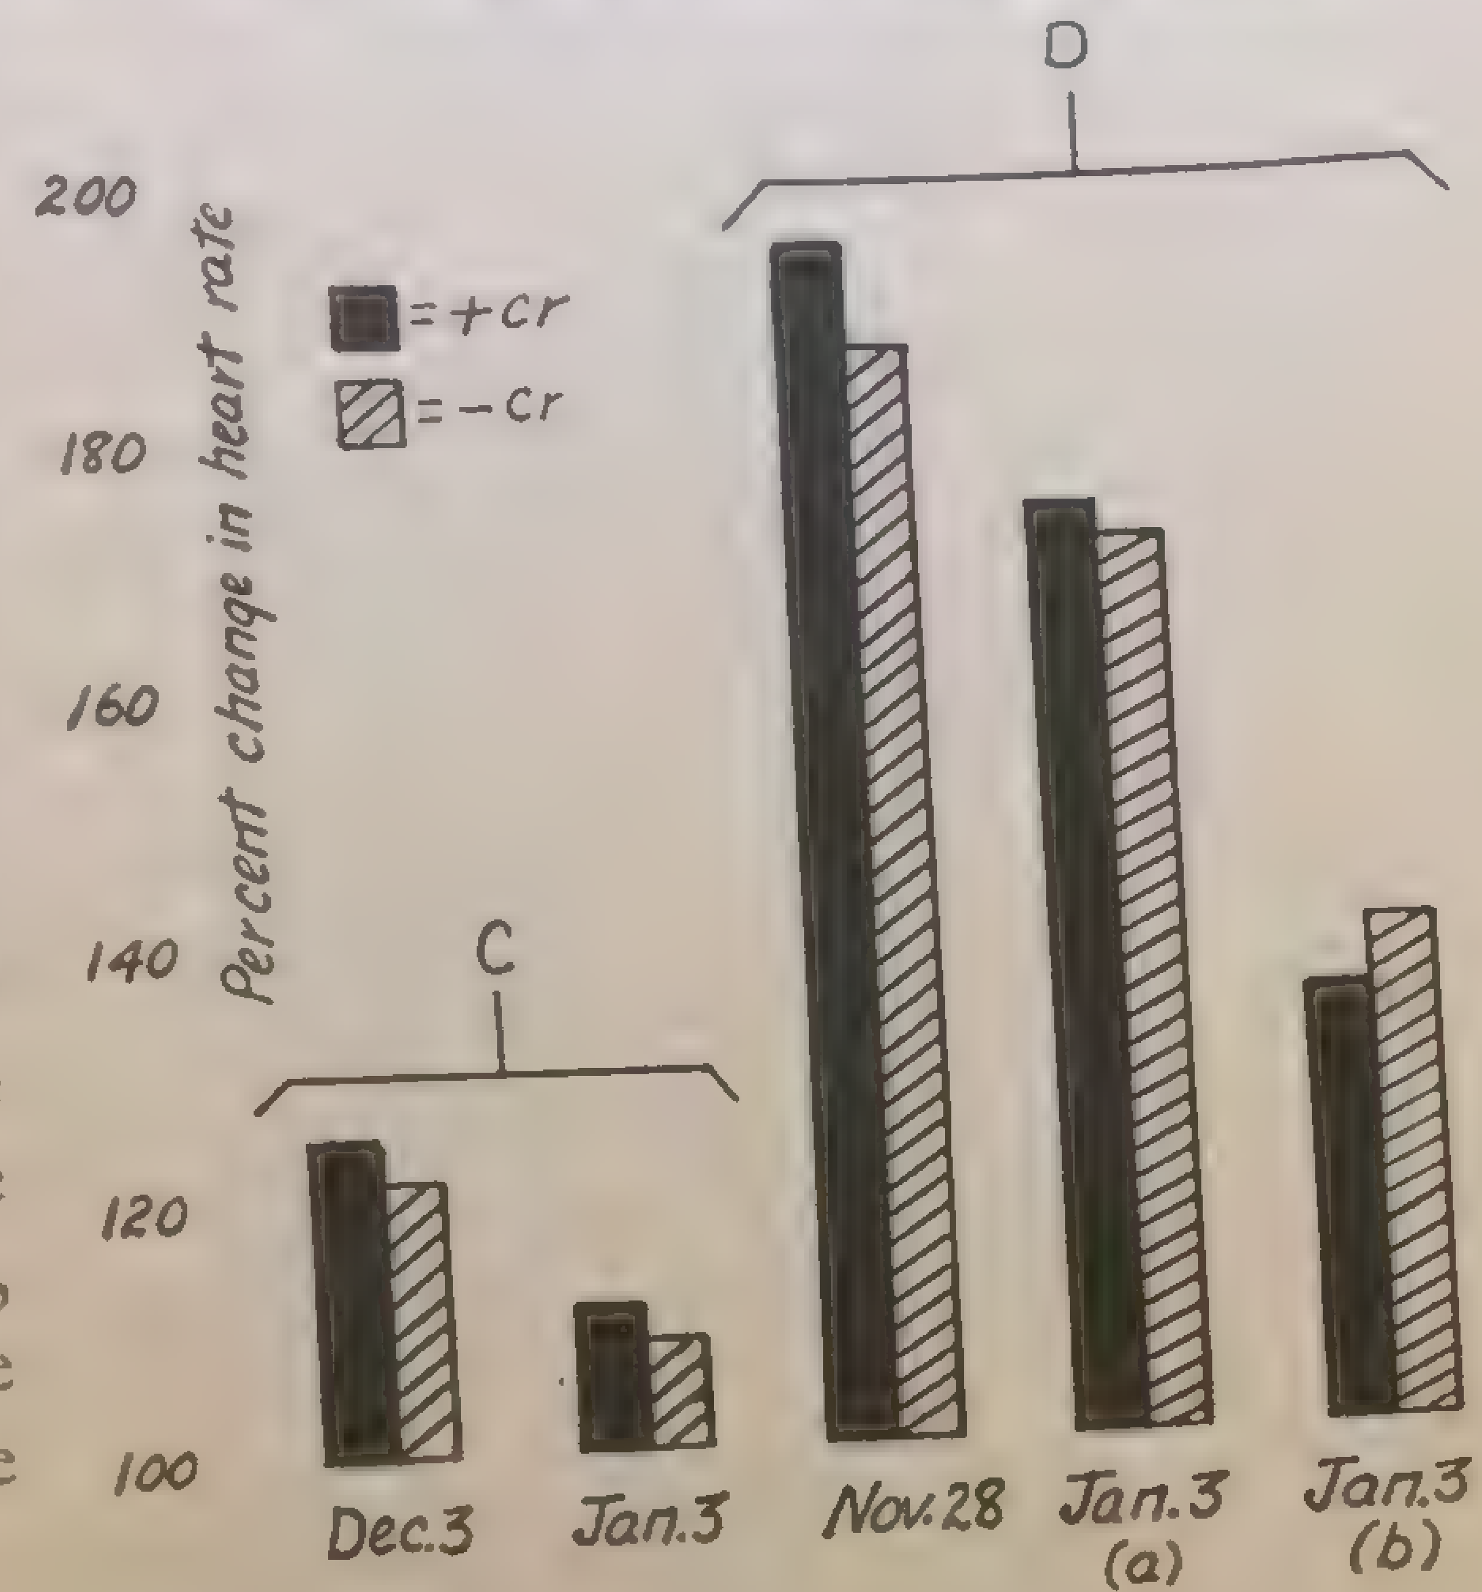

FIG. 37. Conditioned cardiac rates in stable dog (C) and labile dog (D) during strain (Nov. 28-Dec. 3) and during good differentiation (Jan. 3). Control represented as base line = 100%. a = before differentiation on 3 Jan.; b = after differentiation on 3 Jan.

...rtunately heart rates were ...ken on Nick until after ...riod of conflict. The first ...rements were on February, ... On 13 February when he ... the harness on the experi-...l stand a decided increase was noted compared with his heart rate lying ... the camera on the floor. Even then it was striking that when the pulse ... taken by H.S. the rate was faster than when taken by R.B.L. This was in ... with his antagonistic behavior toward H.S. and the rapid change in heart ... whenever H.S. approached—seen throughout the life of the dog, as de-...d in Chapter V.

| | |
|---|---|
| ... 13 February, 1933: (after experiment) in harness in camera: | 132 (R.B.L.) |
| | 145 (H.S.) |
| | 110 (R.B.L.) |
| | 106 (R.B.L.) |
| (after experiment) outside camera on floor: | 144 (H.S.) |
| | 138 (R.B.L.) |
| | 75 (R.B.L.) |
| | 75 (R.B.L.) |
| | 123 (H.S.) |

At the time these readings were made Nick was refusing all food [illegible] the secretory crs to the tones had become zero, and the behavior was [illegible] disturbed (whimpering, retreating, barking).

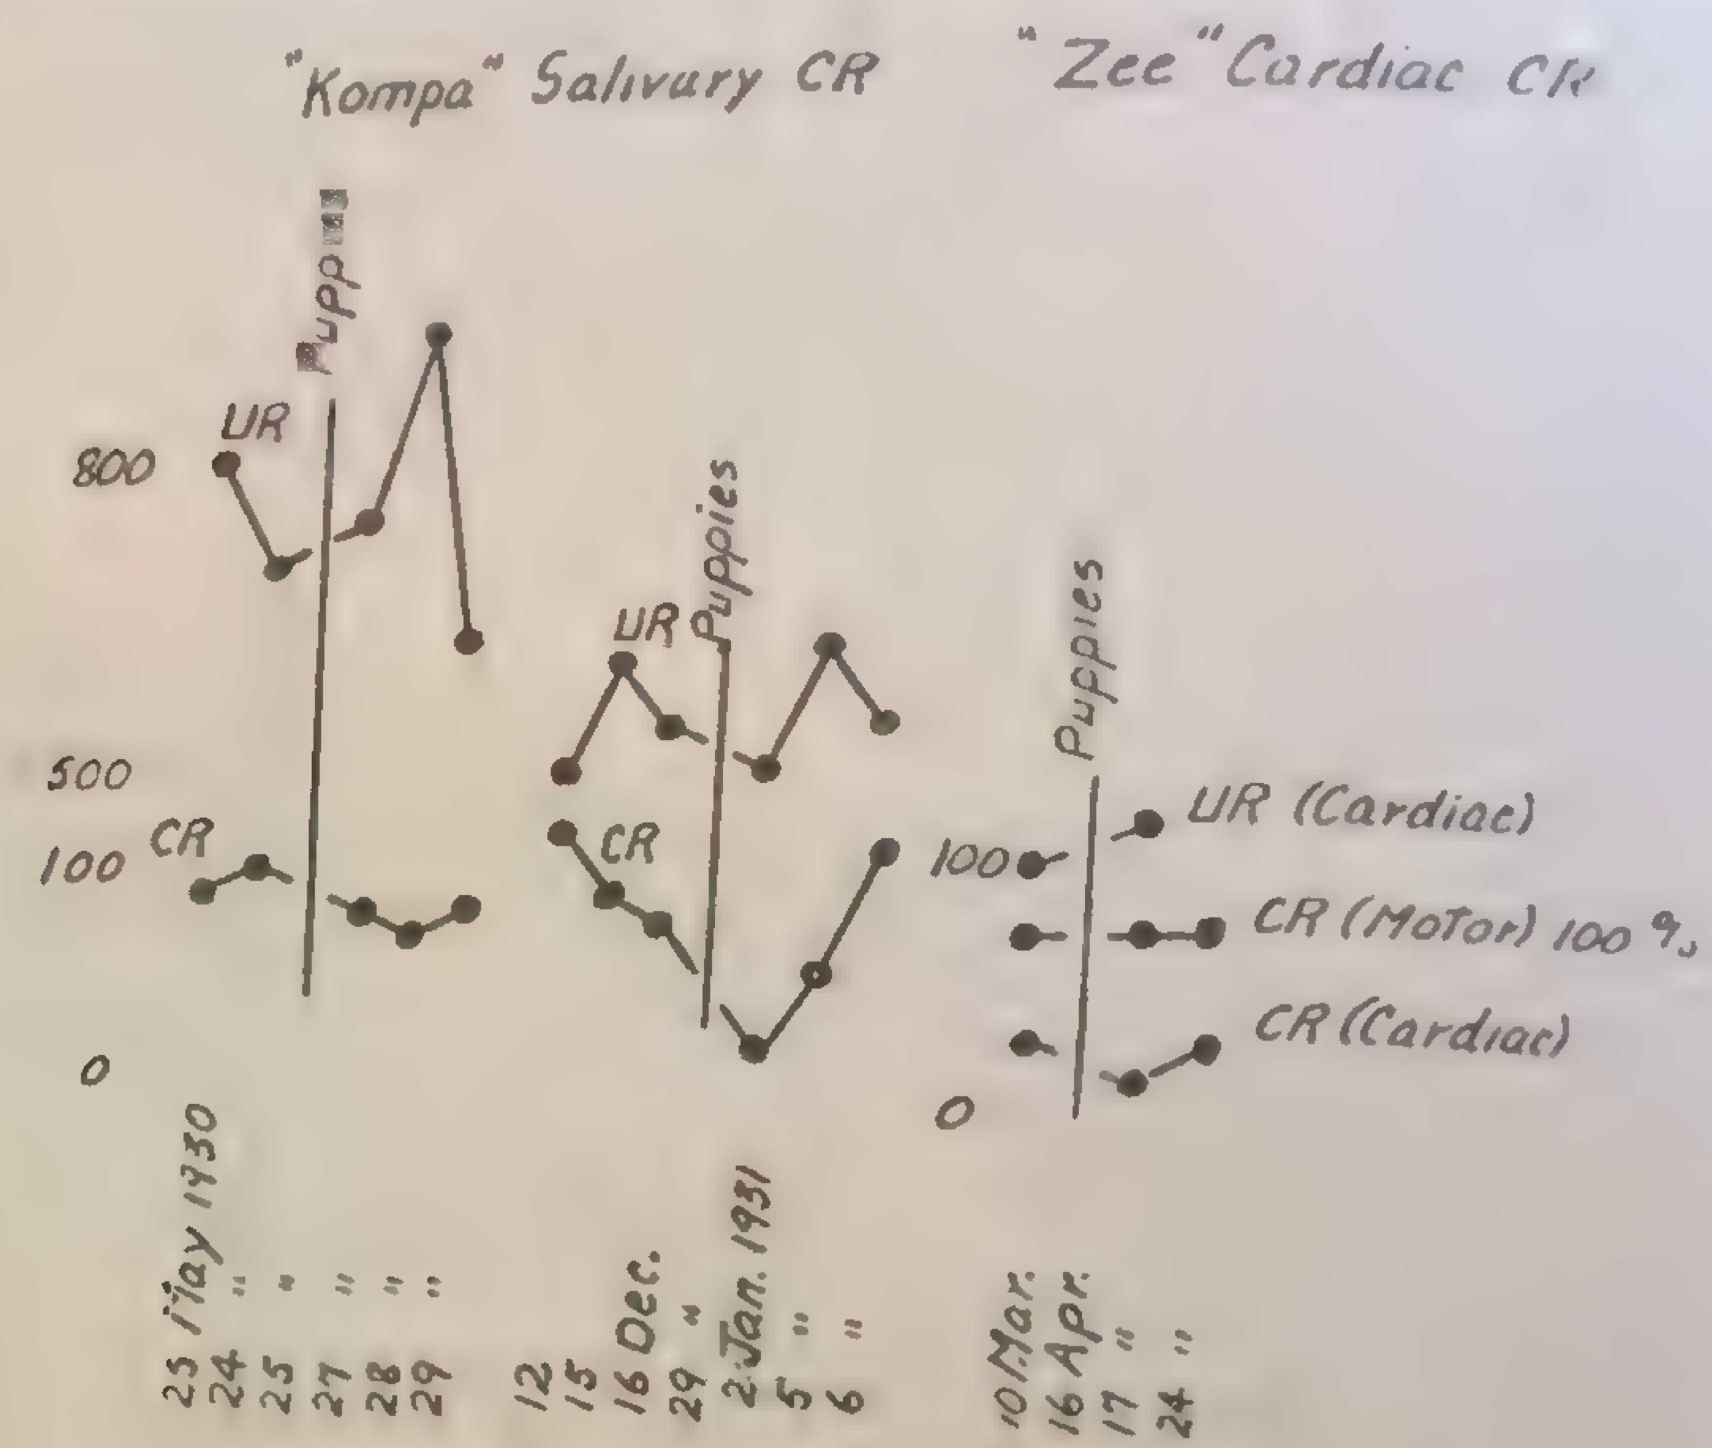

FIG. 38. Effect of parturition on cr.

On 15 February, 1933 the following readings were obtained before [illegible] periment in contrast to the above which were made after the experiment [illegible] camera.

Pulse 15 February, 1933: (before experiment) outside on floor: 87 (R.B.L.)
85 (R.B.L.)
87 (H.S.)

(after experiment) inside camera: 90 (R.B.L.)
116 (R.B.L.)

On 16 February again a marked contrast was seen between the heart [illegible] the dog was lying down inside the camera and when he was in the [illegible] harness in the camera.

Pulse 16 February, 1933: (before experiment) lying inside camera: 100 (R.B.L.)
110 (R.B.L.)
97 (R.B.L.)

In camera with harness attached: 138 (H.S.)

The influence of both person and place is shown by the following heart [illegible] (median of all the experiments):

TABLE 2[illegible]

| | [illegible] | Camera |
|---|---|---|
| [illegible] | 8[illegible] (R.B.L.)<br>12[illegible] (H.S.)<br>[illegible] (H.S. petting) | 106 (R.B.L.)<br>147 (H.S.) |
| [illegible] | [illegible] (Nick alone) | 11[illegible] (Nick alone)<br>[illegible] (Nick alone)<br>138 (H.S. passes in view of Nick) |

[illegible] a striking fact that the heart rate in a nervous condition may depend [illegible] taking the pulse as well as upon the environment; for the rate was [illegible] greater when taken by H.S. than by R.B.L. During our early experiments [illegible] had no recording instruments the personal factor of counting could not [illegible], but later, as referred to below, it is apparent how even the momen- [illegible] H.S. made Nick's heart rate jump 40 to 53 beats per minute, though [illegible] a few seconds.

[illegible] decrease in the heart rate occurred when Nick's ears were rubbed, [illegible] even by H.S. on 12 April, 1933, though he was very restless on this [illegible] Compare for example rate 97 when H.S. is rubbing Nick's ears after the ex- [illegible] with rate 123 when H.S. is simply standing near the dog. The quieting [illegible] comparable to the slow, regular, respiration observed under the same [illegible].

[illegible] Nick's laboratory life, after the production of the behavior dis- [illegible], an increase in heart rate varying from 130-210, was noted whenever [illegible] brought into the experimental environment. The tachycardia apparently [illegible] entirely from the reaction to the environment and was not a permanent [illegible]. Thus in August 1937 his heart rate taken when he was simply standing [illegible] experimental environment ranged from 160-200, while the next day after [illegible] transported to the farm (a distance of 200 miles by train) the rate was [illegible].

[illegible] in the country the heart rate remained somewhat elevated for several [illegible], but after he had been there a year it dropped well below 100 and was [illegible] during the last few months he was on the farm. On 12 January, 1941, [illegible] my side in the country his pulse varied from 80-100. On the 16 January [illegible] after being returned to the city his heart rate measured from 88 to 140, [illegible] this reading was made before he had been taken into the experimental [illegible]. On 27 February, the first day that he was put into his old experimental [illegible], the heart rate varied between 102 and 140.

[illegible] of the specific stimuli connected with the experimental environment [illegible] an additional rise in heart rate. Thus on 27 February, 1941 with the metro- [illegible] his heart rate went up to 152. Attaching the electrodes, as well as the

presence of a person, also caused an acceleration. Even while Nick wa[illegible] country, showing him the food used in the laboratory caused the heart rat[illegible] up to 160, an increase comparable to the sexual reactions to the food [illegible] VI, section 6).

The presence of H.S. continued to elicit a marked increase in heart rat[illegible] as of respiration, as noted before. Even on 16 January, 1941 though he h[illegible] seen H.S. but once for 18 months, when H.S. passed momentarily in front [illegible] window of the room in which Nick was enclosed, Nick's heart rate jumped f[illegible] 80 to 133. The length of time he saw H.S. was not more than a second; the [illegible] in the heart rate occurred in the next heart beat after H.S. had appeared [illegible] window and remained slightly elevated for about a minute, though the sharp [illegible] lasted only 3 to 4 seconds. This effect of H.S. could be regularly demonstrat[illegible] at another time during the same experiment the presence of H.S. caused [illegible] increase from 100 (control) to 140 (with H.S.). (See fig. 14.)

The shortness of the latent period of the cardiac acceleration, i.e., in the [illegible] cycle, which we observed in Nick, has been reported by Gasser and Meek [illegible] in normal dogs during exercise and Whitehorn (*107, 108*) in psychotic patien[illegible]

Whitehorn as well as Hoffmann and I (*42*), found that the cardiac accelerat[illegible] resulting from an emotional disturbance was independent of and added on t[illegible] the acceleration resulting from muscular exercise and that "the degree of accelera[illegible] tion bears little if any relation to the amount of physical emotion." By this Whi[illegible] horn means that the topic about which the patient overtly expresses concern ma[illegible] not be the one which is the source of his main difficulty, though the cardiac rate [illegible] more nearly related to the real conflict. Our findings and those of Whitehor[illegible]

*Gasser and Meek reported in 1914 that the increase of the pulse from exercise could occur i[illegible] first cycle following the clenching of the fist, taking only 1.09 seconds for a 25% increase in ra[illegible] occur. See Gasser, H. S. and Meek, W. J.: "A Study of the Mechanisms by which Muscular Ex[illegible] Produces Acceleration of the Heart." Am. J. Physiol., Vol. XXXIV, no. 1, p. 49.

... the maximum of acceleration comes certainly within a few seconds of ... stimulus.

... Nick's return to the laboratory the heart rate remained low for a few ... did not show as much rise when he was in the experimental environ... had done before. However after he had been back in Baltimore for two ... heart rate in the experimental camera again showed a marked increase. ... heart rates in Nick are in general similar to the findings of Liddell, Par... Anderson (2, 3) in neurotic sheep—irregularity, increased sensitivity, ... under stress, ~~with normal rate at rest.~~ With Nick, moreover, either ... ters or any element of the environment would produce a tachycardia. ... prolonged study of many normal and psychotic patients Whitehorn ... that "emotional disturbances, even of the moderate degree common in ... life, quicken the heart."

... 26 and 27 show the increase in cardiac rate during artificial and natural ... citation in Nick as well as in the normal dogs, Billy and Sechs. ... acceleration of the heart in Nick, as well as in other dogs showing a difficult ... tation, is much greater in the situation of conflict than it is in more natural ... disturbances. Compare, for example, Nick's pulse rate in Table 27 to ... ence of an aggressive male bulldog growling at him and almost allowed ... him, and again that of a cat clawing and spitting at him when placed on ... k, or the faradic shock to the foot, with the accelerated pulse during the ... any elements of the environmental conflict.

TABLE 27

| [illegible], 1939 | Control | Growling Dog | Cat Clawing Back | Sex. Stim. |
|---|---|---|---|---|
| | [illegible] | 133 | 100, 120 | 130 |
| [illegible], 1942 | 110 | cr+ | UR (faradic shock) | Conflict |
| | | | 119 | 165 |

... notable increase in Nick's heart rate as well as in other labile dogs to the ... of conflict over the rates to the presence of real danger (growling bull... clawing cat) is evidence of the greater effect of the former; the highest heart ... served in the camera, was 205, to the bulldog only 140, and to the faradic ... only 130.

Menninger (*84*) states that hypertension in patients is due to an unexpressed ... siveness, for which he prescribes exercise rather than rest.

It is of interest here that when the tone which represented conflict in Nick was ... in the spring of 1942 a cs for a faradic shock, Nick's heart rate in the camera

dropped to about 110, and the rate increased during the faradic shock only to [illegible]

The change in Nick's heart rate under strong emotional stimulation, [illegible] sexual excitation was not so great as the acceleration produced by the situation of conflict.

Our studies of the cardiac response of normal dogs to both painful and food stimuli show a wide variation according to the individual. The latent period [illegible] not be proportional to heart rate. Hence it is clear that the heart rate can not be taken as an absolute index, but together with other measurements it helps to give us a picture and insight into the conflict.

Summarizing, the heart normally shows a quantitative relationship to the intensity of the US and a specific regular change to both excitation and inhibition, similar to the quantitative relationships existing between the salivary CR and US (amount of food). On the contrary, the change in heart rate to pathologic stimulation is chaotic and perverted—without reference to the original significance of the stimuli. It forms part of the picture of the unstable animal under stress, wasting itself by internal friction instead of giving an adequate, regular and quantitative response.[10]

5. Urinary Symptoms

Although the pollakiuria of male dogs is a normal canine habit, it is so unusual for a dog to urinate in the experimental environment, that this symptom is of especial significance. Working with a large number of normal dogs for 15 years, though they might be kept on the experimental stand for 7 or 8 hours at the time, I do not recall a single instance of micturition during experimentation with a normal animal.

Of the several neurotic animals, Nick is the only one that has shown this persistent pollakiuria, although signs of great restlessness appeared in Peter and to a less extent in Fritz under identical conditions of stress. In postpartum female dogs I have noted explosive defecation and urination immediately after the stress of a difficult experiment involving a painful stimulus.

During the year prior to experimentation in Nick no instance of micturition in the camera or antecamera was observed. It is of especial interest that the pollakiuria did not begin during the period of excessive stress (1933) but after he had been absent two years or more from the active work of the laboratory in 1936—nearly 3 years after the period of acute stress. The pollakiuria became prominent about the time that the dog in estrus was first brought into the camera with Nick, and

[10] It is possible that the apparent chaos is due to the lack of our ability at present to make quantitative measures of all the factors in the pathologic situation, but it seems more likely that the pathologic response, involving an organism under *excessive* strain, beyond the ability of the animal to react appropriately, is characterized by variability, just as are many other pathologic reactions.

...ed until the present, appearing whenever he is brought into the experi-
...environment, or when *elements* of this environment are present, such as
...H.S. approached him even when Nick was on the farm.
The course of this symptom after 1936 was in general parallel to other symp-
...of the disturbance. The worst period was 1936 and 1937 before he was taken
...farm. The record was about 30 times in 25 minutes (1937) while running
...the camera. Punishment was entirely without effect; after whipping he
...run to another part of the room and urinate immediately. Pollakiuria began
...the elevator and the corridors when H.S. was bringing him toward the
...environment.

...symptom is apparently connected in some way with the pathological sexual
... It is probable also that it is an expression of natural sexual excitation
...as it was enhanced by the presence or even the olfactory trace of a female
...

...the two months' rest in the country and subsequent return to the labora-
...pollakiuria in the experimental environment reappeared (13 October, 1937).
...erections also first appeared in the same period.

...on the farm ameliorated these symptoms, particularly while Nick was in
...country, but also after he was returned to the laboratory. During the first part
...month sojourn on the farm (1938) pollakiuria still occurred when I
...Nick into the house with me, but toward the end of the period it disap-
...—for the first time in 3 years—even though Nick was in the room with
...the same time he was perfectly quiet and showed no evidence of disturb-
...

...though after returning to the laboratory in 1941 Nick has shown great im-
...ment in this respect, the symptom has reappeared, and has been at times
...ed though not so much as previously. The trace of a female in estrus
...always evoked micturition—several times in the spring of 1941 and on
...experimental stand. This is an extraordinarily rare manifestation for even a
...dog.[11]

...events which incite the general restlessness also aggravate the pollakiuria;
...the instances on the farm when he went through painful experiences, such
...dragged a distance by catching his foot in a tow chain (1937).
...is a frequent symptom of nervous disturbance particu-
...enuresis (Hamill [52]) is a frequent symptom of nervous disturbance particu-
...in children, a fact which the Freudians have emphasized. It is often noted in
...as a result of punishment or frustration; a colleague told me that it oc-
...in his 5 year old girl when a sister was born; English children sent to the
...country and separated from their parents have been reported as frequently enuretic
(Partridge, M.B. [91]).

[11] ... (*11*), Masserman (*83*) and others have reported abnormal micturition in cats.

Pollakiuria is a sign of sexual excitation in normal dogs, e.g., see the note for 27 October, 1942 where the behavior of a normal stable male (Bamech) in the presence of a female in estrus was almost identical with that of Nick in the situation of conflict.

The close association of pollakiuria and erections in Nick in the environment of conflict would also be easily comprehensible on the basis of the proximity of the centers controlling the two acts and the involvement of the genito-urinary as well as the cardiac, respiratory and related centers during a state of general autonomic spread such as occurs in Nick.

The psychoanalytical evaluation of pollakiuria, defecation, erections as aggressive reactions is supported to a certain extent in Nick by his urination on the food used in the experiments to produce conflict. An alternative explanation is that outlined by Ischlondsky: that the spread to the autonomic system occurs on a physiological principle of proximity and that later (perhaps during psychoanalysis) the act is associated with aggression, somewhat similar to the process of rationalization.

## 6. Sexual Symptoms

The appearance of the pronounced sexual manifestations and the reciprocal relations to nervous disturbances constitute a definite and important chapter in experimental neuroses. Sexual excitation as an expression of nervous disturbance has been seen in several of our laboratory dogs, but most prominently in Nick. They may occur either during the actual period of strain, or may be absent then and occur months or years later from the trace of the conflict.

The sexual manifestations may be summarized as follows: 1) the environment of conflict, including the isolated elements of the environment as well as the people involved *provokes abnormal* sexual excitation; 2) conversely, the effect of the environment *inhibits normal* sexual function produced either by artificial or by natural stimuli; 3) paradoxically, the effect of natural sexual excitation—as well as human companionship—*dissipates* the neurotic manifestations as well as the artificial crs; 4) *reciprocal time relations* are seen between sexual excitation and other physiological excitations, such as food excitation; 5) neurotic sexual symptoms are chaotic in character (irregular, etc.); 6) *pathologically conditioned sexual excitation* differs from the normal sexual crs.

1) *Sexual excitation as a manifestation of the nervous* disturbance was first forced upon my attention by the persistent appearance of the sexual erections in Nick when he was brought into the environment of conflict. Since this time I have noticed such erections in several other dogs. In the frontispiece and in fig. 39 Nick is seen giving a typical anxiety-like reaction with marked erection to a tone used in the camera in 1938.

FIG. 39. Nick during tone. Note the anxiety-like facies, with labored breathing, tugging on leash, sexual erection. Cf. fig. 8.

...al sexual erection can be ob... male dogs under certain ..., particularly during the ... in young or timid animals ... or when a stranger ap... the experimental room. ..., however, are of short ... appearing irregularly and in... and are markedly different ... persistent and chronic sexual ... some neurotic animals.

... out in the chapter on Con... Reaction Types, the appear... sexual erections is dependent not ... the situation of stress but also ... individual. Thus Nick was the ... of the series of three dogs sub... the same severe stress who gave ...unced change in sexual symp... well as in other physiological ... That it has been possible to see ... other dogs, however, that sex... occur with stress is evident from the following example. ... whose stability was marked, in contrast to Peik and Nick, began to ...xual erections when brought into the environment where the differentia... become difficult or impossible.

...: On 12 November, 1940 elaboration of crs to bell on the basis of induction shock ... started; he formed this cr after three trials; became stable after 20 trials. On 19 ... M100 was introduced as a negative cs (not accompanied by shock); stable dif... was immediately formed. On 25 November M60 was introduced as a positive ... differentiated from M100; stable differentiation followed almost immediately. This ... the stable type, judging by records of respiratory and cardiac crs. On 27 December ... and negative metronomes were brought closer together (by changing the positive ... to M69); a stable differentiation was quickly formed. On 13 January, 1941 ... was replaced by M88 (+) with stable differentiation. In two weeks M88 (+) ...ted by M92 (+) with stable differentiation by position but not by absolute fre... the metronomes. In February the effect of benzedrine was tried on the motor as ... the sexual reflexes. In March M88 (+) and M100 (—) were differentiated ... as well as by pattern.

When the differentiation became too difficult, so that the dog gave identical

reactions to both the excitatory and inhibitory metronomes, sexual erections [illegible] to occur, and continued as long as there was difficult differentiation.

On 10 March, 1941 M96 (+) was introduced, there was poor differentiation [illegible] from M100 (—) is a well-nigh impossible differentiation]. On 14 March sexual [illegible] were first noted in Connie when he was brought into the camera, although he had [illegible] no er erection to the elicitation of sexual URs in February (on the [illegible] 12, 13, 14, 15th). Sexual erections on bringing the dog into the camera were [illegible] the following days: 15, 20, 21, 25, 26, 29, 31 March, 1, 2, 3, 4, 5, 8, 9, [illegible] April, [illegible] time was started the study of metrazol on crs. During all this period the [illegible] differentiate between M96 (+) and M100 (—) hence on 19 March M[illegible] replaced by an easier differentiation viz., M92 (+) which was also not [illegible] metrazol was being used on alternate days, and M92 (+) and M100 (—) [illegible] sexual erections occurred when he was brought into the camera but less frequently [illegible] ments of Dr. Victor Rosen).

Experiments on differentiation M92 (+) and M100 (—) continued until [illegible] without success, however; the introduction of 10 metrazol convulsions in this [illegible] April and May apparently abolished the abnormal sexual erections.

In contrast to Nick this dog developed sexual erections *during* the [illegible] difficult differentiation—not as with Nick, some years afterward (fig. [illegible]).

Under normal conditions, in the early part of Nick's stay in the laboratory [illegible] the farm and after his return in 1941, Nick appeared to be active and [illegible] sexually. However in 1932 when in the paddock with Fritz and a female in [illegible] Nick in contrast to Fritz showed a submissive attitude and no sexual activity. [illegible] stances have been mentioned, throughout his history, of normal and even [illegible] ently hyperactive coitus; as late as 1940, he exhibited sexual activity toward [illegible] male dogs, and in 1942 when over 12 years old he copulated vigorously [illegible] females in estrus.

The abnormal sexual erections elicited specifically by the environment [illegible] flict came considerably later than the other pathological reactions. At first there [illegible] general definite changes in activity, extreme restlessness, inhibition of the food [illegible] (as early as 1933); later appeared the stereotyped respiration, the pollak[illegible] (1935, 1936) and finally in 1937 the pathological sexual erections—first [illegible] on 20 May, 1937 to the sound of the metronome. At first infrequently, [illegible] erections appeared oftener, not only when the dog was taken into the ex[illegible] mental camera and to the auditory stimuli used there but to isolated eleme[illegible] this environment. Thus while on the farm in 1939 the presentation to Nick [illegible] the kind of food which had been used in the camera resulted more than [illegible] immediate micturition on the food, and sometimes erection with ejaculation. [illegible] the *social factors*—the presence of those who worked with him, particularly [illegible] but also W.H.G., even in a remote environment as on the farm—repe[illegible]

[illegible] with ejaculation. It is remarkable to note that these reactions [illegible] by close blood relations of the people who worked with Nick, the [illegible] close relatives of W.H.G., just as he had shown negativism to the [illegible] H.S. As the erections were never noted to any other people, there is a [illegible] that olfactory resemblances exist for the dog with members of the [illegible] family.

[illegible] pathological reactions instead of disappearing with time became firmly [illegible] more frequent. However, they were never observed except when some [illegible] of the old environment was present. It would therefore seem that they [illegible] specific reactions. The only other time that such abnormal sexual erections [illegible] was, as noted in the history, during the specific pattern of whirling, [illegible], and defecation when Nick was first taken off the leash; also in females [illegible] urination and defecation have occasionally been seen in the experi-[illegible] room.

As pointed out earlier, the *pathological* sexual erections persisted with great [illegible], while it was possible to produce artificially in the laboratory only very [illegible] and fleeting normal sexual erections by the ordinary cr technique. This is [illegible] contrast to the ease of producing experimentally crs based on other [illegible], e.g., pain and food.

[illegible] are to be found in both animals and human beings. Klüver (personal [illegible]) found that the cebus monkey masturbates and practises fellatio [illegible] cannot solve a problem, and C. F. Jacobsen (*91*) says his chimpanzees [illegible] with a difficult problem sit and masturbate.[12] Ischlondsky (*57*) has [illegible] masturbation in school children during examinations and in solving [illegible] mathematical problems; Matte notes ejaculation in neurotic children. [illegible] (*91*) saw a patient who began to have frequent and persistent erections [illegible] sister married and who later got married himself to cure them but with-[illegible]. W. Halsey Barker has told me of a nervous patient who had erections [illegible] ejaculation and subjective feelings of anxiety when he talked to his em-[illegible].

A patient of Dr. Victor Rosen's (anxiety) preceding his depression had erec-[illegible] with ejaculation when he walked in the part of the town near his home, [illegible] he had satisfied his homosexual drives. This patient previously had had [illegible] factory sexual relations with his wife who finally refused sexual intercourse [illegible] him. During his depression the patient experienced lack of libido and inability [illegible] erections (cf. with Nick in camera). Cobb reports frequent sexual neuroses [illegible] patients suffering with anxiety (*91*).

[12] [illegible] (*91*) believes the temporal lobes in monkeys have specific inhibitory centers for sexual [illegible] removal results in masturbation and sexual hyperactivity.

For other instances see the discussion by Ischlondsky in the final chapter of this monograph.

From the above facts it is evident that in several dogs pathological sexual erections arise in the environment of conflict. Now we shall see what effect this environment has on normal sexual excitation produced by adequate sexual stimuli.

2) *Effect of the environment of conflict on normal sexual function.* After it became apparent that there existed a reciprocal relationship between the state of conflict and sexual excitation, experiments were performed to determine more exactly the effect of one upon the other. For this purpose we compared the effect of the camera, i.e., the working environment, on normal dogs (Billy, Pat) with Nick. The normal animals, although subjected to difficult differentiations in the camera, were stable animals who had never shown any permanent disturbances of behavior. Besides comparing the effect of this environment upon Nick and the normal dogs, experiments were done on Nick to determine the effect of the camera in contrast to that of the antecamera as well as to that of a neutral environment.

The sexual excitation (including erection, orgasm and ejaculation) was produced both by artificial means and by the presence of female dogs in estrus. Owing to the specific advantages of the artificially produced sexual excitation as a method of measurement, to be outlined in another paper, most of the data are drawn from such experiments.

Artificial sexual excitation can be evoked by peripheral stimulation (faradic) applied to the external genitalia for a given length of time. Such peripherally acting stimuli proved adequate for the initiation of marked sexual erections, accompanied by ejaculation of semen in most dogs. During the first experiment with Nick on 10 June, 1937, after 9 minutes of peripheral stimulation, 5 cc. of semen were ejaculated. In subsequent experiments with a constant period of stimulation (one minute) the items measured were the latent period of ejaculation, the time at which erection of the penis became complete, and its duration. The results are shown in Table 28 and fig. 43. From these it is evident that the camera had a much greater effect upon Nick than upon normal dogs. In Nick the latent period of ejaculation was markedly shortened (from 14 seconds to 6½ seconds),[a] the beginning of erection was slightly decreased and the complete duration of erection was greatly diminished (from 210 seconds to 73 seconds). In the two control dogs the effect of the camera was in opposite directions, slightly excitatory in one, slightly inhibitory in the other, but in neither dog were the changes nearly as marked as in Nick.

Further evidence of the effect of the camera was seen in Nick after his rest in the

[a] Figures given are median values.

After the first removal to the farm for two months, on return to the [illegible] the inhibitory influence of the camera was slightly less than formerly [illegible] the longer rest of 18 months the camera had no inhibitory influence on [illegible] reflexes (fig. 40).

The influence of the working environment and of the rest in the country on [illegible] sexual reflexes is parallel to the influence of the environment on the respiratory anomalies and on the cardiac rates (see fig. 10).

Although the number of observations on the effect of the environment on . . . are too few to warrant positive conclusions, in the beginning of 1941 it was . . . that the duration of Nick's copulation with a given dog in estrus was . . . delayed when the dogs were placed in the antecamera, i.e., when they were . . . to the environment of conflict, as compared with another floor of the building.

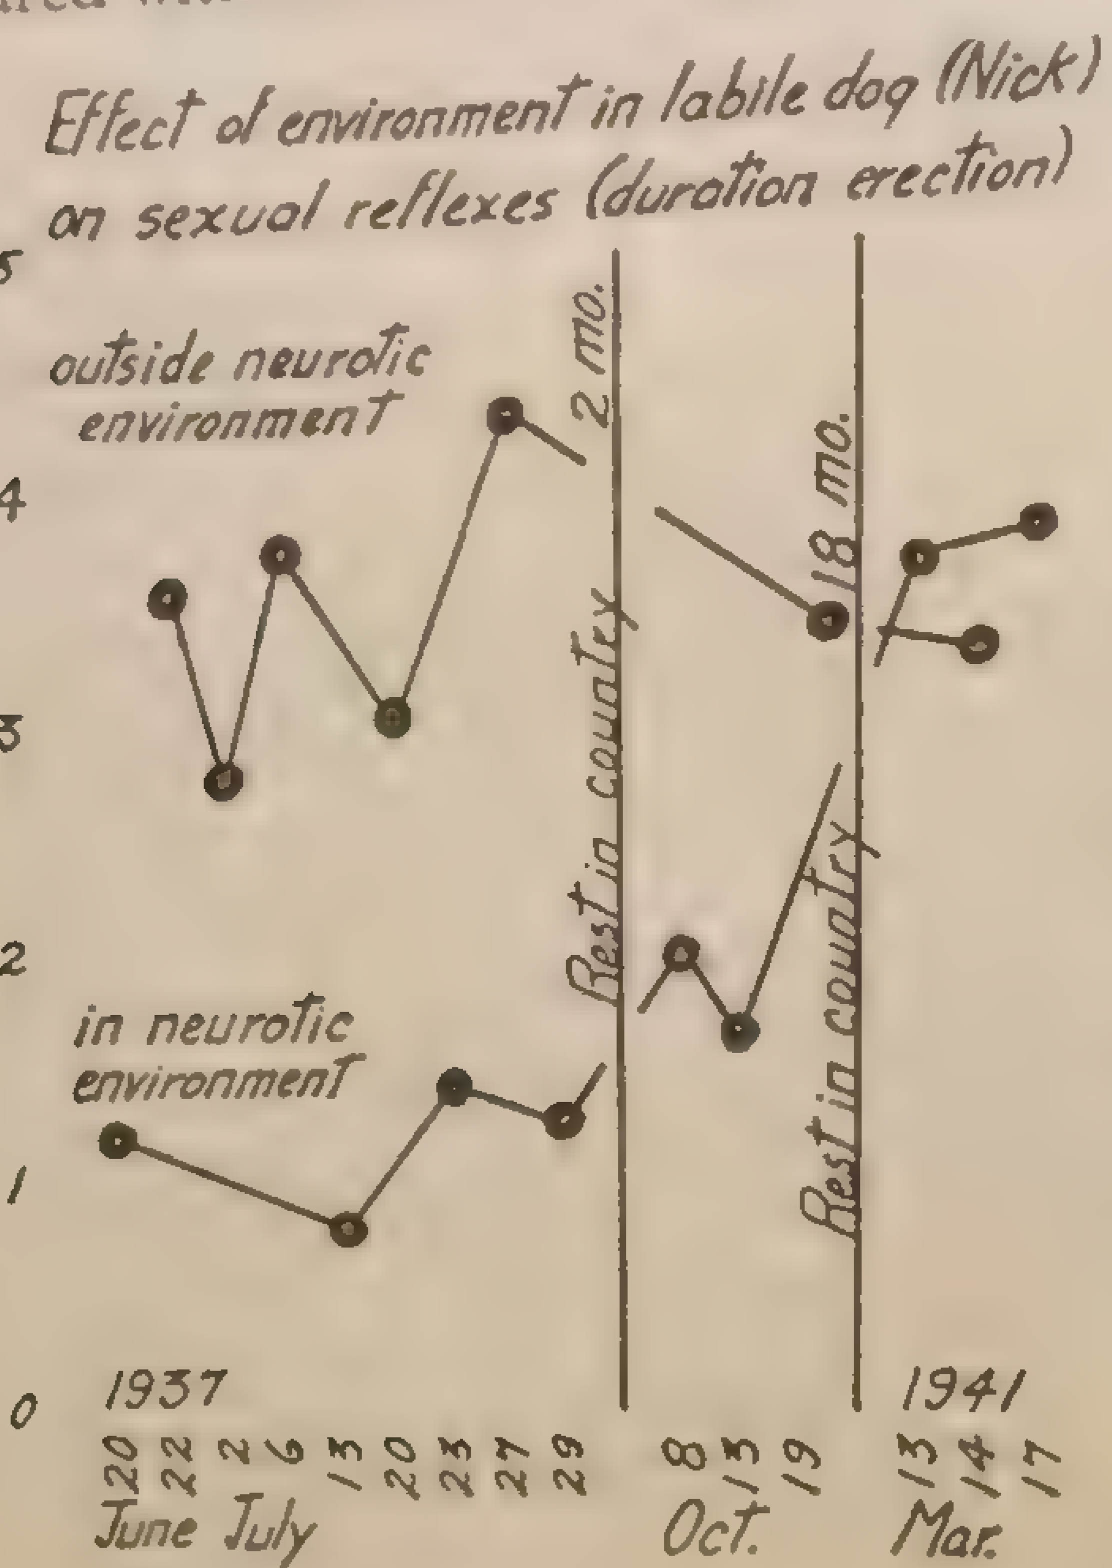

FIG. 40.

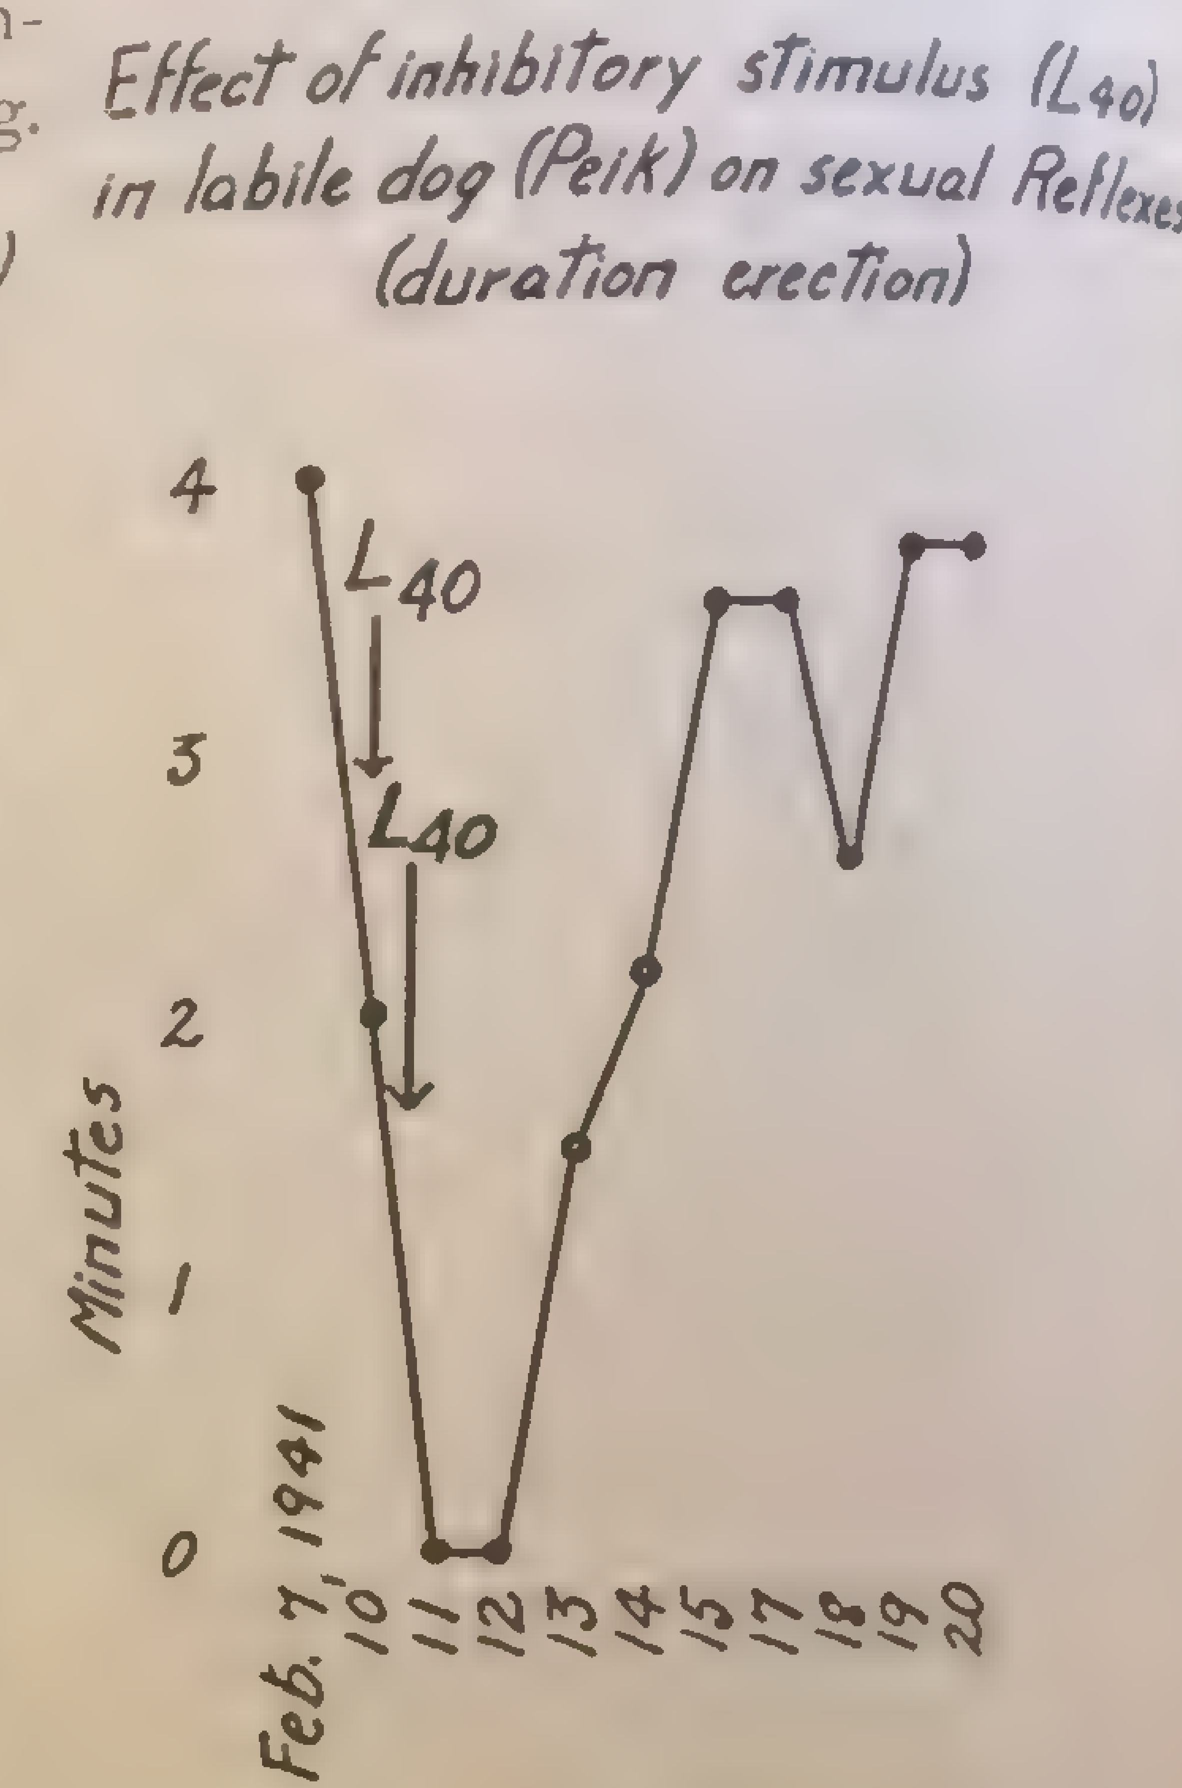

FIG. 41.

Peik was a dog who on casual observation appeared normal in the first year of work in the laboratory (1939), but who later seemed moderately labile. During this time he was subjected to the ordinary cr elaboration and differentiation. After he had been in the laboratory for 18 months and when subjected to the strain of introducing one more cs to those he had already been accustomed to, he began to show sexual erections, but on the contrary, the sexual reflexes to normal . . . fell to zero.

Peik had been differentiating between M100 (+), and M80 (−). A new cs L60 (+) was introduced; after he failed to react to L60 the sexual reflexes to normal sexual stimulation disappeared as shown in fig. 41. When L60 was removed the sexual reflexes returned.

There was a disturbance in heart rates as follows:

Peik, 12 February, 1941. "Control heart rate = 90; during new disturbing cs . . . The respiratory record also shows an inhibition of the respiration with L40 (the new cs . . .

... caused by L40 is shown not only in the inhibition of the cardiac and respira- ... the inhibition of the sexual reflexes."

... started in the laboratory in November 1939 with the formation of a cr to M120 ... 1 December Bu (+) was differentiated from M40 (—). Differentiation had ... 23 January, 1940. During this time the dog was quiet. Beginning in Feb- ... sexual reflexes were measured. On 12 February, M100 (+) was given alter- ... M40 (—); but differentiation was still poor by 23 March, although there was ... cr to Bu. Differentiation had been accomplished between M40 (—) and ... 30 March after 229 repetitions of M40 (—) and 133 repetitions of M100 ... routine of Bu (+), M40 (—) and M100 (+) was repeated daily until 22 ... when the dog's metabolic rate was measured in the camera by fastening a respira- ... his snout; these measures continued until 3 June, when the routine of the ... resumed. In January 1941 Peik began to refuse food occasionally, though he ... quiet and maintained the differentiation. During this month M40 (—) was re- ... M60 (—) making the differentiation more difficult, and when this had been ... on 29 January M80 (—) replaced M60 (—). On 1 February this differen- ... failed to be accomplished, though the dog frequently appeared sleepy. On 5 February, ... differentiation was started between L100 (+) and L40 (—). Sexual reflexes were ... measured on 7 February, 1941, and throughout February. By 19 February differen- ... between the auditory stimuli was maintained but no positive cr had been formed to ... About this time the dog often refused food. From 26 February until 19 March ... convulsions were given, resulting in loss of differentiation between M100 (+) ... (—).

... ) and L100 (+) were introduced on 5 February and used without the auditory ... until 14 February. With Peik the change of the routine from well differentiated ... to a monotonous repetition of a new stimulus L40 (+), coincided with the loss ... reflexes, which gradually returned to normal when the different auditory stimuli ... introduced, as shown in fig. 33.

... tence, as well as abnormal sexual excitation is, according to Rennie, a fre- ... manifestation in various psychoses, especially in paranoia but also in schizo- ... (1 : 3).

*The effect of complete and natural sexual excitation on the neurotic* mani- ... and on normal crs. Obversely, there was a reciprocal relation between ... excitation accompanied by orgasm whether artificial or naturally produced, ... the "anxiety-like" state. My attention was first called to this inhibition of the ... in 1936 when Nick was placed in a paddock with a dog in estrus. During ... period, and for a week or more afterwards, we noted that Nick was much ... when brought down into the camera, that the defense reactions were ... markedly diminished (whining, barking and restlessness), and that he ate much ... readily in the antecamera than in the camera. These observations first led ... the detailed plan of experimentation on the reciprocal relations of sexual ... excitation and the neurotic manifestations.

The effect of the companionship of the dog in estrus on Nick proved to be much greater than our planned attempt to transform the environment by giving Nick all of his daily rations (meat) inside the camera for a period of 5 [illegible] instead of the usual feeding in his paddock, away from the laboratory.

This effect was evident also in the reduced 24 hour activity.

Not only placing Nick in the same paddock with the female in estrus during the whole day altered his behavior in the camera, but sexual excitation, [illegible] natural or artificial initiated in the camera, completely inhibited the "anxiety-like" behavior. Thus when a dog in estrus was brought into the camera, the tone, which usually evoked definite reactions (whining, barking, restlessness, [illegible]) was completely without effect. However, this dog had to be brought within [illegible] feet of Nick on the stand; then he began sniffing and paying attention to her instead of to the tone. That this was a specific effect is shown by 1) the [illegible] of proximity to Nick and 2) the following fact: this same dog brought [illegible] time after the period of estrus had absolutely no influence, when placed in the camera with Nick, in preventing the "anxiety-like" behavior. Nor was it possible by the presence of any other dog, male or female not in estrus, to dissipate the neurotic behavior. As will be pointed out later, a person petting Nick, or sometimes even standing close to him had a similar though lesser effect than the dog in estrus on the neurotic behavior. (See respiration record, fig. 42.)

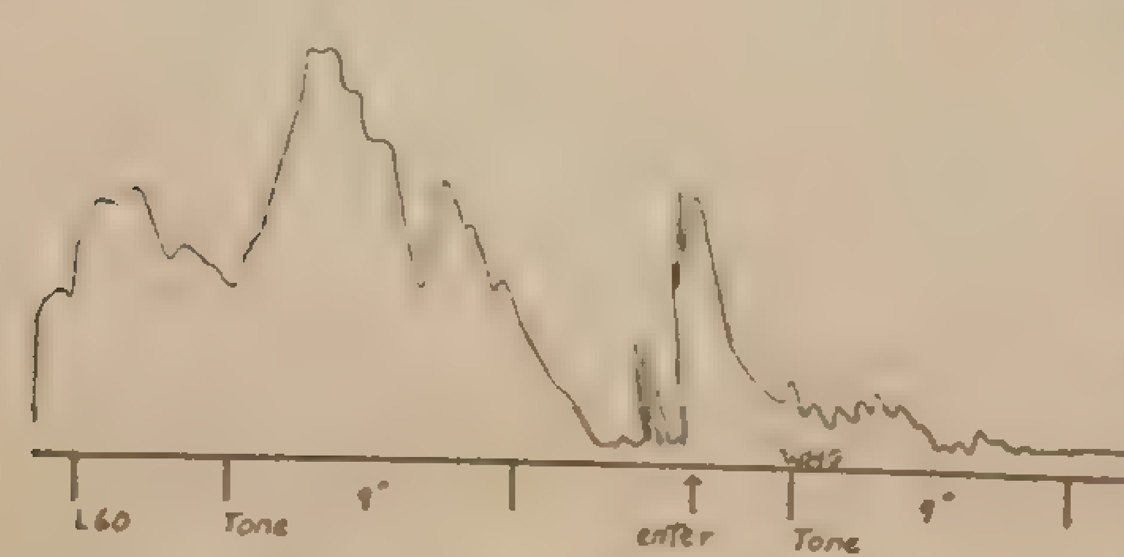

FIG. 42. Quieting effect of person in camera with Nick. Example of fourth type of respiration.

Sexual excitation produced artif[illegible] had the same effect upon the "anxiety-like" reactions, i.e., there was a [illegible] "refractory" period of some minutes after sexual stimulation when the anxiety producing csi were without effect, as described below. Moreover the effect [illegible] temporal distance from the sexual excitation could clearly be seen just as [illegible] distance from the tone was a factor in the intensity of his defense responses.

4) *Reciprocal time relations.* Several experiments were made which [illegible] that artificially induced sexual excitation with orgasm had a definite inhibit[illegible] effect upon the anxiety state. One of these was as follows (10 June, 1937[illegible]

"13:45 Tone tried twice at two minute intervals; each time there are defe[illegible] movements, backing off, whining and a marked erection. On the first trial, [illegible] erection lasts about 30 seconds (T given for 20 seconds). On the second tri[illegible] T, the erection lasts about 75 seconds, the penis protrudes about 5 cm. beyond [illegible] prepuce. 14:00-14:09: peripheral sexual excitation produced marked [illegible] (penis protruding about 12 cm.) with ejaculation 5 cc. semen; erection subsi[illegible]

When T was tried during sexual stimulation at 14:05 it was without ... Nick; no evidence of the defensive movements nor even of the orienting ... Nick paid absolutely no attention to it. Also when T was given at 14:10 ... no defensive movements whatever. 14:14: T given 20 seconds—no ... movements but Nick orients by turning his head, but does not shift ... T at 14:22: defensive movements shown by backing off, but there is no ... and the defense is not as pronounced as before sexual stimulation. 14:49: ... weak defense reflex. 14:51: T (20 seconds) gives moderately strong ... movements; Nick backs off, whining slightly; erection for 40 seconds." ... instance the tone was given for 20 seconds (fig. 43).

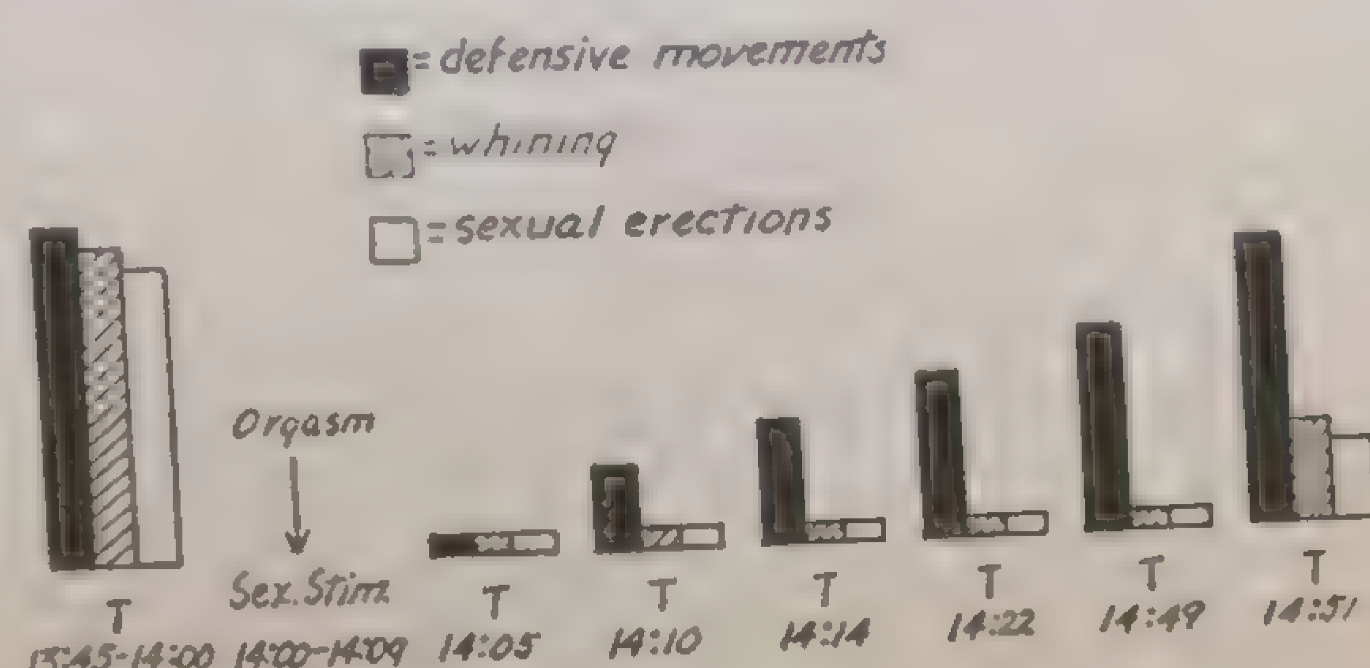

FIG. 43. Inhibitory effect of sexual stimulation with orgasm on anxiety reactions to tone (T) in Nick as manifested by defensive movements, whining and pathological sexual erections. Cf. with figs. 1, 7, 31, 32.

... above experiment offers ... evidence for both the effect of the tone in producing ... sexual erections, and ... of adequate sexual ... in dissipating the ... reactions to the tone. ... it is clear that such artificially produced sexual excitation ... a limited temporary effect and furthermore that this in... after-effect lasts only a ... minutes, disappearing gradually and not abruptly.

... 11 June, 1937, when sexual excitation was initiated at 15:30 o'clock by ... for 1 minute, a record of the respiration made at 16:10 is corrobora... of the effects noted on the previous days—viz., that the obsessive defense ... occurring to the tone given at 16:10, 16:11, 16:12 and 16:13 are not ... so pronounced as usual.

... sexual stimulation, used at intervals from 1937 to 1941, was never ... have any effect on the dog's subsequent behavior other than the fleeting ... tory" period as noted above.

... comparing the intensity and duration of the after-inhibition (on defense re... ... from sexual and other forms of excitation (food, social, etc.), it is seen ... sexual excitation has by far the greatest influence, next in order is the social, ... finally the food, which has very little effect. This relationship can be more ... seen in the acute "refractory" period than in the permanent effects; owing ... complicating factors in the prolonged experiments the effect is difficult to evalu...

Likewise there is in Nick an inhibitory after-effect ("irradiation") of sexual ... on the food excitation; thus on 25 February, 1941, it was noted that

Nick would not take food during coitus, nor for some minutes afterward. This relationship, however, did not hold for the female with whom he was copulating, who accepted food even during coitus, nor does it hold for all male dogs. Thus, though in Nick it appears that the sexual excitation is much stronger than other excitations, or at least has the power of inhibiting other reactions, the same relationship does not necessarily exist for all dogs. It may indicate a sexual labileness in Nick comparable to his general autonomic labileness.

As noted in Chapter II and also in Chapter V (Nick 26 October, 1942) sexual excitation has a marked inhibitory effect on both the food crs and URs in normal male dogs besides Nick.

Since performing these experiments on Nick it has come to my attention that Maiorov (80) has made experiments confirmatory of ours on the reciprocal relation between sexual excitation and motor and salivary crs. He used a bitch in estrus, and he found the same effect on the crs of a male dog whether the male dog was simply together with the female in the camera or whether he was allowed to copulate with the female. Instead of showing complete inhibition of the crs as did Nick, Maiorov's dog exhibited various phases of hypnosis. Maiorov explains the inhibition as an effect of negative induction proceeding from the sexual center to the cortical centers for the crs.

Examples of the strong inhibiting effect of sexual excitation on other physiological functions abound in Nature: such for example as the abstinence of the salmon from food in the breeding season. The glukharka (great grouse of Russia) is reputedly deaf while he is singing but only during the mating season; during his song then the hunter may walk boldly beneath the tree where he is sitting.

I have recently observed a clear cut instance of the acute inhibitory state produced by sexual excitation in the earthworm. Ordinarily when these animals are feeding they are very alert, withdrawing immediately into their holes in the soil at the slightest movement of the observer even when he is several yards away, reacting probably to certain vibrations through the ground, for they do not react to sound. However, when the worms are copulating, which they do by applying their inferior surfaces closely together for a distance of 3 or 4 cm., they give no response to an approaching observer though he may be standing within a few cm. of them, nor even to a slight tactile stimulus, especially if this is applied to the copulating end of the worm. The worm remains abnormally sluggish for one or two minutes after copulation is interrupted.[14] All these observations I noted repeatedly on different days in the spring months of 1938 and 1939.

A long refractory state of the whole organism following sexual stimulation thus seems to be a general characteristic of the sexual function in many species. This

[14] W. Horsley Gantt: Experimentally Produced Sexual Neuroses. In press.

...the basis of the general postcoital suppression which has been observed: ...'s post coitum triste."

...tence of a state of non-reactivity is not, however, peculiar to sexual ... I have shown previously that after each type of stimulation there is an ...ndition for that particular stimulus (See Ch. IV, section 5). Whether ...n is more like the refractory state of the peripheral nerve after excita- ...more similar to what Pavlov describes as negative induction cannot be ...y the present experiments.

...rest here are the observations of Pavlov on both increasing as well as de- ...the sexual excitation in dogs. The former method (carried out by ligation ...minal duct and simultaneous grafting of the gonad from a young animal) ...in the disappearance of neurotic symptoms and the return of the condi- ...flexes to normal; this improvement lasted for 3 months (*89*, p. 57). ...d Bard note that the injection of estrogen (as well as the state of hunger) ...ticate cats raises the threshold for rage and fear (*91*).

...sely, the weakening of the sexual reflexes through castration paves the ...a neurosis in animals of a certain type, viz., the strong type, but not in ...l-balanced nor in the weak types. Pavlov's explanation is that castration ... inhibition (already deficient in the strong excitatory type); in such ...d dogs he has obtained a state which he considers analogous to paranoia, ...: the responses to only certain stimuli are abnormal. Both Pavlov's and ...nd Bard's facts fit with the phenomena seen in Nick.

...*haracter of the sexual symptoms.* As pointed out in Chapter VIII (Consti- ..., variability of reactions, as well as stereotypy, is a pathological attribute. ...is seen in the range of cardiac, respiratory and secretory responses. The same ...erved in Nick concerning the sexual reflexes, which varied in duration from ...1 to 20 minutes, while in the normal dogs the variation was usually be- ...1½ and 3 minutes.

...hol also had a much more pronounced effect upon sexual reflexes in Nick ...n any other dog (see figs. 48, 49).

...e abnormal symptoms in Nick which apparently continued from day to day ...period of 6 years—restlessness, pollakiuria, erections and rapid breathing, ...rn of defecation—are closely similar to what has been seen in stable dogs ...normal sexual excitation. Thus on 26 October, 1942, other male dogs ...Nick in the same paddock with a female in estrus behaved almost identically ...Nick does whenever he is brought into the experimental environment. This ...argument for the fact that Nick's neurotic symptoms bear a relationship to ...manifestations of normal sexual excitation.

...) *Pathological sexual crs.* A large number of experiments were carried out in ...k and other dogs by the cr technic (a cs plus sexual excitation) in order to

produce artificial sexual crs. However this has proved very difficult, [illegible] occasionally have definite sexual crs to a neutral stimulus [illegible] other hand, as seen above, sexual reflexes often occurred in [illegible] as a result of a conflict, and thus it may be stated that sexual [illegible] conditioned as a component of the pathological process. This is [illegible] parable to other experiments from this laboratory, e.g., with adrenalin [illegible] trating the fact that it is easy to condition a change when the [illegible] state of excitation is set in motion, but almost impossible when a [illegible] ditioned is produced by a peripheral stimulation without central excitation. Thus salivary secretion can be conditioned to a food excitation but not to pilocarpin[illegible] (Finch [24]); gastric secretion to food but not to histamine (63); hyperg[illegible] to emotional states but not to the injection of adrenalin (36). Althoug[illegible] duction of sexual reflexes by peripheral stimulation undoubtedly has [illegible] component, this is probably not so strong as the normal stimulation of [illegible] in estrus.

Without laying too much stress on what may be only a superficial analogy I should like to point out the following striking similarities between the [illegible] states produced by sexual stimulation and by the stimulus of petting Nick [illegible] ing him behind the ears). In both cases there is a definite and rather similar [illegible] in heart rate. Secondly the type of respiration during petting is almost identical with that during the final stage of coitus,[15] as shown previously (see figs. 34, 42). Thirdly each emotional state is followed by a "refractory" period of non-re[illegible] toward the anxiety-producing stimuli. (See figs. 12 and 43.) This peri[illegible] reactivity is much longer with sexual excitation than with the social fact[illegible] sexual excitation the refractory period lasts about 10 minutes and includ[illegible] reactivity toward food, while with the social excitation it is only for some [illegible]

It has been pointed out previously how much more intense and stable are [illegible] pathologic cardiac and sexual crs in this state of "anxiety" than they are [illegible] natural, adequate situations, such as the real danger of another dog [illegible] forms of sexual stimulation.

The predominance of the cardiac responses and the abnormal sexual exp[illegible] (erections, etc.) in the pathologic anxiety-like state of Nick and their [illegible] and greater stability in comparison with the normal cardiac and defense [illegible] parallel to the marked intensity of these reactions when they occur as comp[illegible] of a clinical pathologic state resulting from conflict.

[15] The character of the respiration changes during the various stages of sexual excitat[illegible] stages it may be increased and irregular, but during the final stages, which may [illegible] respiration becomes markedly quiet—deep, slow and regular—similar to what it is during [illegible]

BEHAVIOR

...f the dog's not standing so close in structural development to homo ... the apes, and the larger gap between man and the dog in the anatomy ...us system than between man and the apes, domestic animals in general ...n particular have special advantages for a study of psychopathology ...d by other animals. These result from his most intimate relationships ...man and his role as the only willing slave to every caprice of his master. ...mesticated animals he is the one most generally accepted as a member ...n family. This advantage of the dog is seen in the laboratory when we ...t he willingly submits to experimentations necessitating his standing ...tion as long as 8-10 hours, such as for example in the Pavlovian studies ...of pancreatic juice, and that he will even jump on the stand and remain ... his master inserts a needle into the vein to withdraw blood. In the dog ...t have to overcome a natural antipathy and suspicion toward the human ...we do in most other animals. Furthermore, although the dog possesses ...s and habits which are perhaps closer to those of the human than any ...mal, he has not that marked investigatory interest, restlessness and in... of the primates and of man himself, which make the latter poor ...for experimentation.[16]

...h his association with man lasting thousands of years, the dog has lost ...is lupine attributes and has adopted instead several of his human master, ...ving made a nice sociological adjustment to living in the human family. ...the cow and the horse are oriented about their habitual home but it is the ... than any other animal whose affections are directed predominently to the ...regardless of whence his food comes.[17]

...my own experience in the laboratory as well as from common experience,

...ming crs on monkeys in Pavlov's laboratory in 1926 I observed a monkey who, having ...ed to receiving grapes with the raising of a red flag, performed an experiment on the ... by reaching through the bars and raising the flag himself!

...of this came under my eye in 1934. An American Pit bull terrier was transferred to ...ing in the laboratory for about a year. During this time I had made a salivary fistula in ...d his salivary crs perhaps 10 days, but seldom seen him otherwise except for taking ... for one night. But he took a decided fancy to me: whenever I went to the farm he ...mediately and would run 1/3 of a mile from the caretaker's house to meet me at my ... everywhere, sleep outside my door at night and not return to the caretaker's house ...during the two or three days that I was there (though I had no food for him), and when ...would trot, as fast as he could for several miles after the car. Many similar instances are ... the dog will not eat after the bereavement of his master and may even grieve himself to ...significant, as we have shown in this laboratory, that the dog actually remembers with ...tionally, much longer than with his muscles and secretions as measured by the crs and ...r part of his life than the human being.

there is evidence that the dog is more closely oriented toward his human companions than toward his canine fellows. Studies on the pathological animals confirm this view.

Owing to the strong natural social orientation of the dog about the human and particularly toward his master, he is an excellent animal in which to study the altered behavior arising from a disturbance in social relations.

With the above facts in mind regarding the dog's peculiar relationship to the master and the role of the human being in the dog's life, the observations of disturbance in these relationships as seen in Nick and other dogs appear highly significant.

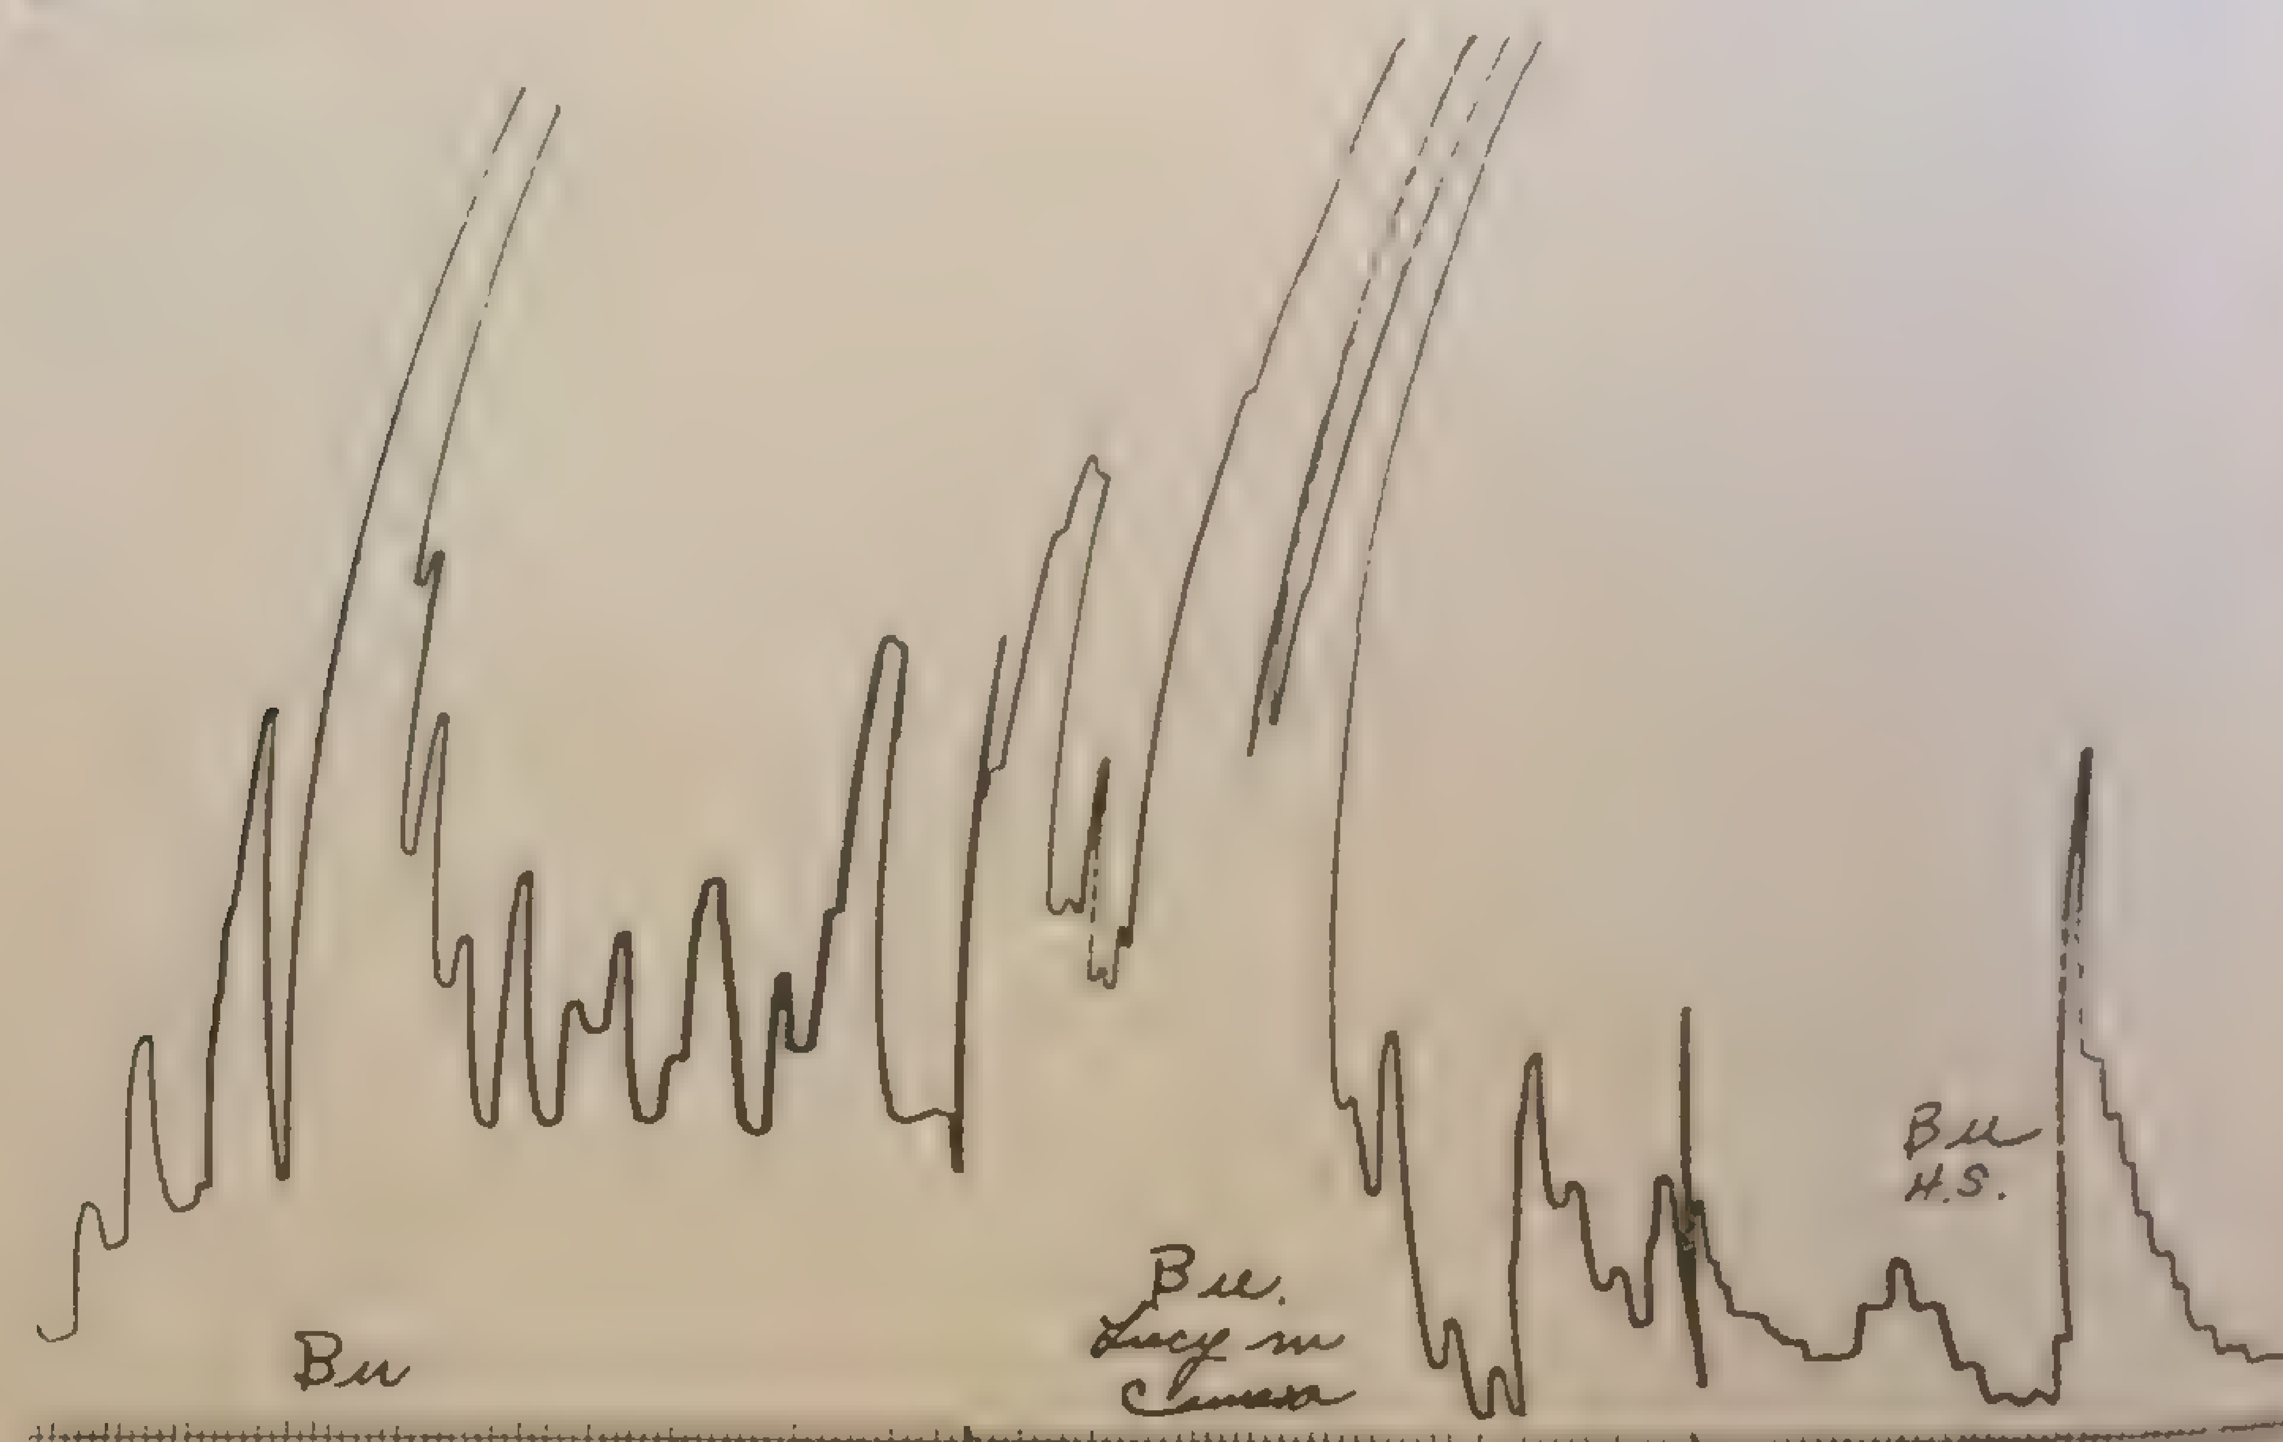

FIG. 44. Comparative effect of dog (Lucy) and of human (HS) on anxiety in Nick; HS [illegible] anxiety reaction to Bu. (19 Jan. 1938.)

Certain pathological changes have also been seen in the relationship of disturbed dogs to the other canine members of the group. Among the causes of such disturbances are severe, prolonged fights among themselves, as have been pointed out in Billy and Kompa, Blue and Lady (Chapter III); the labile animals but not the stable showed marked changes in their behavior. Also in Nick the effect of females in estrus has been striking. I have pointed out under the discussion of sexual relations that the same dog (Lucy) when out of estrus had no effect upon Nick (see fig. 44). Another example of a canine relationship which may be a potent cause of disturbed behavior, measurable in the crs (shown by temporary loss of recent cr

...s the human factor in both the amelioration and aggravation of the neu...ate, the behavior of Nick toward his canine and human companions is ...nt.

...ly in Nick's laboratory life he was seen to be submissive and retiring in a ... other dogs. Thus in April 1932, a note on the behavior of Fritz and Nick ... in a paddock with a dog in estrus showed that Fritz was bold and aggres... ...ile Nick sat in a corner by himself. At other times later during his life Nick ...d marked aggressiveness (barking, bristling up) toward other dogs, but ... chiefly bluff as he rarely fought. Jealousy toward other animals was seen ... farm, but this too is a trait of normal dogs.

... of the early manifestations of pathological behavior seen in Nick was his ...r fawning toward those who worked with him. He would turn over on his ...e to the feet of such a person, or wrap himself around their feet, and then ...t in slowly crawling up their legs, in spite of being pushed away. This type

of behavior has been noted throughout the life of Nick, directed particularly toward those closely associated with him in the experimental environment but [illegible] to the people outside of this environment, for example those on the farm and those next to the laboratory.

Pavlov reported the same type of behavior in a dog after the changed procedure of the experiments had made him neurotic.*

Pavlov describes his dog as follows:

> Now we produce the [illegible]. [illegible] the inhibitory [illegible] only [illegible] seconds. In the following experiment we prolong it for [illegible] five minutes. [illegible] day we repeat the five minute inhibition, and this was enough to change radically the [illegible] dog, to make him actually ill.
>
> Of the regularity of the conditioned reflexes there remained not a trace. Each day showed a characteristic picture. All the positive conditioned reflexes were markedly diminished, [illegible] completely disappeared. The inhibitory were disinhibited. Sometimes the [illegible] phase set in, i.e., the positive stimulus was inactive and the inhibitory one differentiated [illegible] it gave a positive effect. During the experiment the dog was extremely restless, [illegible] breathing vigorously, very restless, [illegible] marked [illegible] to the slightest fluctuation of the environment. Frequently he refused the [illegible] given after each positive conditioned stimulus. In a word, concerning the work with conditioned reflexes there was no doubt of an extreme, chaotic condition of the nervous activity. The same was manifest in the behavior of the animal. Putting the dog on the stand and preparing it for the experiment, and also removing it was not easy; for the animal was [illegible] and uncontrollable. *When free he conducted himself very strangely; when lying on the floor he would turn on one side and crawl up to some one, which he never did before.* The *Doctor* who took him to and from the kennel reported that he had become [illegible] (p. 95).

This description applies closely to Nick. A marked and seemingly paradoxical characteristic of Nick toward those with whom he worked was his negativistic attitude. Whenever there was anyone else in the laboratory besides H.S. or W.H.G. he would immediately run to the stranger in preference to the others, and then he would not be induced by any means to approach either H.S. or W.H.G. The greatest antagonism was toward H.S., who was most closely associated in the experiment with Nick, and apparently next toward W.H.G. Very pronounced in Nick was this negativistic reaction toward other members of the families of the two collaborators who worked most closely with him. Negativism was not apparent toward other persons.

*It was not until the publication of this [illegible] in [illegible] that I knew of Pavlov's [illegible] parallel between his dog and Nick was so striking I call attention to the independence of our observations [illegible] to believe that neither report was the result of suggestion—either as [illegible]

spiration reveals this ambivalent attitude of Nick toward his human s. He often reacted to H.S. as he did to one of the conflicting stimuli , 44). Here is seen the deep inspiration and the prolonged step-like ex- But on the contrary a human being standing by and petting him had a quieting influence as shown by the slow smooth respiration (fig. 12). same person could either elicit the anxious type of breathing, by simply before the dog, or dissipate it by petting him. The corresponding influ eart rate of a person has been referred to in a previous section (Table 25, It is seen that the presence of W.H.G. although eliciting the anxious n inhibits the subsequent reaction of Nick to the tone.

ely analogous instance was noted by Pavlov in 1924 in a dog whose crs hed due to an emotional shock (flood). When Dr. Speransky, his master, ly in the room with the dog he began again to take the food. Even if an f Speransky's clothing were placed in the room with the dog though not the animal's reactions became normal (*88*). This example from Pavlov s my observation that the effect of members of the same family may be nt upon olfactory similarities.

ilar example is the quieting influence of a person being in the room with during the early period of experimentation.

st striking example of this negativistic attitude was seen the first day of rrival on the farm in 1937, when I met him at the station and walked him ore a mile to the house. Not only did he not exhibit any friendly feelings recognition of me, but he actively pulled away and tried to escape, hardly his head toward me during the whole walk.

wever by kindly treatment and especially close companionship with Nick on rm this negativistic attitude toward me was finally, after about a year, re- d. He retained it toward H.S., however, to a milder degree when H.S. came farm, though he had never seen him before in that environment and had en him at all for over a year.

e the normal dog runs avidly toward his master always in preference to rs, whom he may or may not avoid, this negativistic attitude in Nick is the remarkable.

emporary negativism, lasting only several days, toward the master was seen ter in other dogs as a result of the natural emotional shocks, as noted in Chap- III, particularly with Blue. This dog—a rather shy, vacillating type—slumped corner by himself and refused to walk with the experimenter after the pain- de.

Besides the evidence of this negativism in the purposeful movements, it was ed also on the autonomic level. Thus in the presence of the experimenters Nick showed marked increases in the respiratory and cardiac rates, pollakiuria, as

well as marked sexual erections and even ejaculation in the presence of people who had been associated in the experiments with him.

### 8. Generalization of the Neurotic Behavior

In the process of Generalization for both the normal and the neurotic animal the experimental milieu becomes a cs for the crs. This has been emphasized in the previous pages of Nick's history—how approaching the experimental camera or any element of it elicited the neurotic behavior. The effect of the camera can be seen in the heart rates, general behavior, etc.; figs. 45 and 46 show the readiness with which Nick accepts food on the farm in contrast to his behavior in the camera. Liddell has also found that sheep made neurotic to a certain room do not show the symptoms in another room (personal letter, March 1942).

It was possible in Nick to see a detailed and specific elaboration of neutral csi into pathological csi, as the following account shows:

Somewhat similar to the stage of generalization in the elaboration of crs is that of the neurotic behavior. During the period of formation of a cr to a certain signal, e.g., a metronome, the animal reacts to an undetermined

Fig. 45. Nick eating greedily on farm, 1940.

Fig. 46. Nick accepting food from attendant on farm, 1940.

range of similar auditory signals, thus metronomes of all frequencies, various clicks, etc. Only after a period of differentiation—reinforcement of one metronome by the US (food or shock) and failing to reinforce the other metronome—does the animal give a specific conditioned reaction. As a rule this state of generalization results in a cr only to stimuli closely related physically, e.g., all metronomes,

... the animal that is learning to react to a metronome does not ... stimulus as different from the metronome as the tone.

Nick, however, once the pathological disturbance became fixed to the ... virtually all auditory stimuli, though they had not been used previously ... produced almost the identical pathological pattern as the tone. The ... stimuli as far removed from the tone as air bubbling through water, ... or a person whistling.

... stimuli had never been given in the pathological environment, the ... to them may be considered as the result of a general lowering of ...

... type of spreading of the disturbance could be seen—resulting from a ... between a new and neutral stimulus and any one of the above ... It was first noted that Nick began after several repetitions of my ... H.S., "All right Harry give the tone," to show the typical pattern of ... movements, etc., including retreating, whining, panting, erections. ... this it was planned to carry out the systematic elaboration of the ... behavior to a more exact cs. Light being very dissimilar to sound and ... the nervous system through a separate analyzer, a light flashed 40 times ... (L40) was selected as a secondary cs for the tone. In February 1938, ... repeated a number of times in ... while Nick was on the stand, ... whether it was neutral. Nick ... response to it except for a slight ..., i.e., a normal reaction. On ... February, 1938, L40 was given for 15 ... and after 5 seconds of stimulation ... L40, a tone (1000 cycles) was ... for 10 seconds. Thus L40 was made ... T1000 by 5 seconds and then ... were both given together for 10 ... An examination of the record ... February shows that on the 20th ... the pathological disturbance ... to L40, 3 seconds after its beginning, and the same reaction to L40 reappeared again on the 22nd and 23d trials.

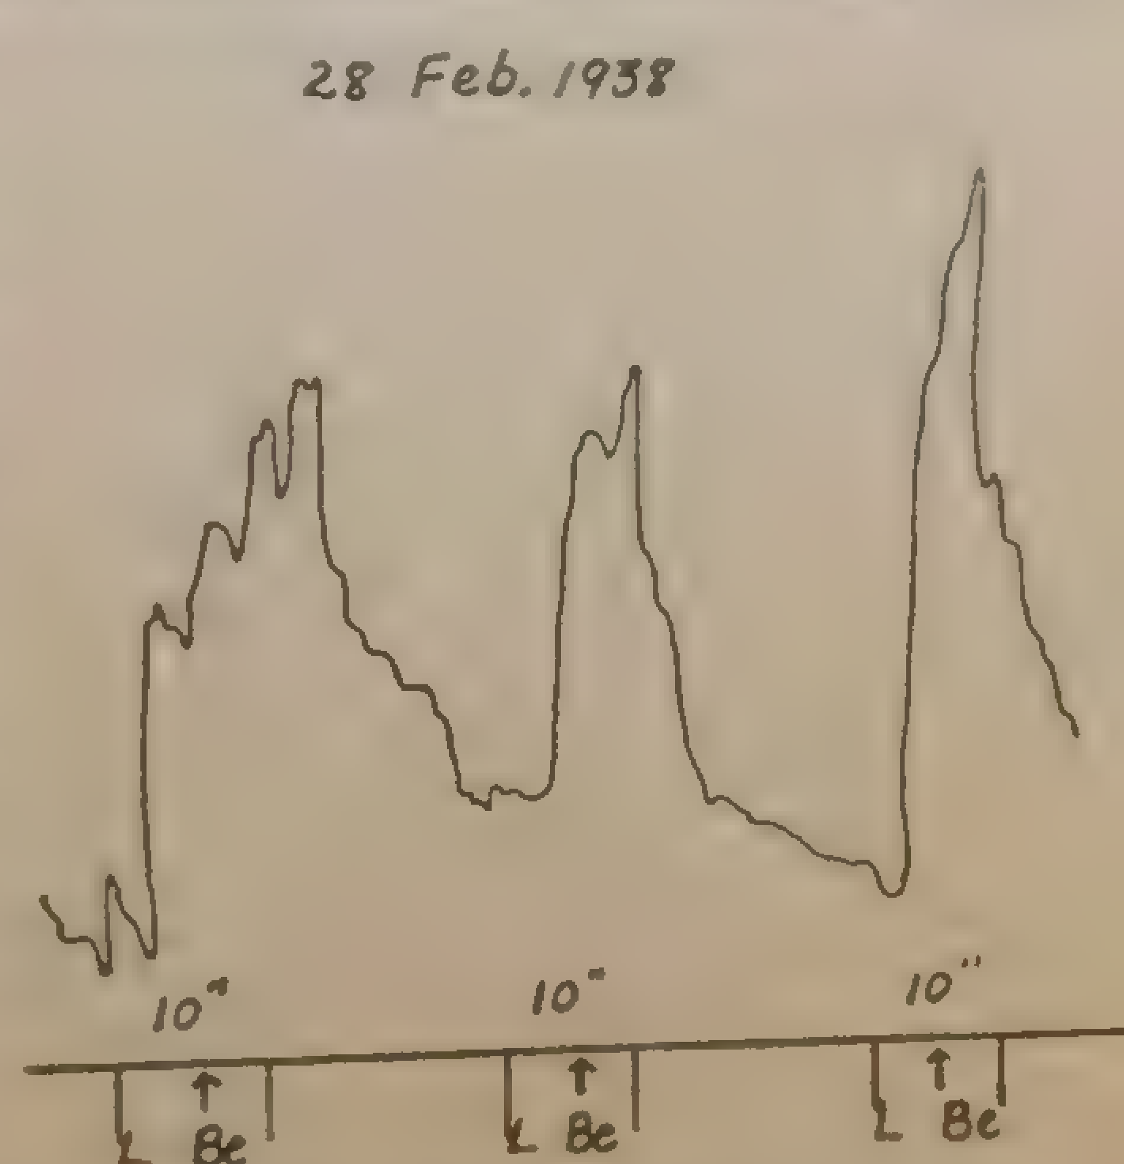

FIG. 47. Respiratory reaction of Nick to light and bell. Note respiratory crs begin several seconds after L.

... 24 February the pathological pattern which had appeared to L40 on 24 ... had been lost. In order to restore it L40 was accompanied in the same ... using, however, the bell instead of the tone. After 11 such combinations the ... began again to show the pathological reactions to L40—which he continued ... for the next 7 combinations (fig. 47).

That the acquired pathological behavior to L40 is weaker than to the auditory stimuli is shown on the 13th, 14th, 15th and 19th combinations of L40 with Bc for that day where the pathological behavior to L40 but not to Bc is irregular and completely dissipated by petting.

Nick was not experimented with again until 7 April, 1938. On this day L60 was used instead of L40 to see if generalization in the visual stimuli was present similar to the generalization seen among the auditory stimuli. It was found that pathological reactions to the light were retained for this period of 6 weeks, and that also generalization from L40 to L60 had occurred. An examination of the chart for this day shows that when L60 is used alone on the first 3 trials there is a decided reaction. From the 4th through the 11th trial L60 was combined with T1000; the reactions to the latter were more pronounced and more certain than to the light.

It is noteworthy that the pathological reaction to the light often has a longer latent period (usually 3 to 5 seconds) than to the auditory cs (less than 1 second) (fig. 9). This would indicate that L may simply serve as a signal for one of the pathological auditory stimuli. The question arises whether the light is simply a signal for the tone or whether it has itself acquired the same properties of the tone.[19] The former alternative is probably the correct one for the following reasons: the reaction to the light does not start at the beginning of the light as it does with the tone, but usually 3 to 5 seconds after the beginning of the light, and, when the light is given alone, the defense reactions are much more marked toward the end of the 5th second, which is the time when the tone usually is added. (See respiration record, fig. 9.)

No experiments were performed between 14 April and 6 May; on this day it was seen that Nick retained the pathological reactions to the light over this three week period.

L40 was next tried on 26 October, 1938; the only reaction then was a slight orienting one, showing that retention of the pathological responses had not lasted this long. But on 9 December, 1938, one combination of L60 and an auditory stimulus was sufficient to restore the pathological reactions to the light.

In comparing the speed of elaboration of the pathological reactions to a new stimulus (L), as well as the stabilization of such newly elaborated pathological responses and their retention, it is evident that the pathological pattern is much more quickly formed, requiring few trials, and much more stable in its appearance and longer retained than are the normal crs to either food or pain. The comparison is so striking as to leave no doubt concerning the ease of forming the pathological crs.

[19] The answer to this question might be given in normal animals by extinction of the auditory crs, but extinction of the pathological processes was not possible in Nick.

form of generalization, perhaps olfactory, was seen in the defense re Nick to the close relatives of the two people (W.H.G., H.S.) who were associated with Nick (Ch. V).

...nism by which these new pathological crs are elaborated may be com Pavlov's higher order crs, although the experimental procedure by which ...ned is somewhat different. In forming the higher order food crs the ...s given a few seconds subsequent to the neutral stimulus, and after a ...ber of such combinations the neutral stimulus becomes a cs equivalent ...ary cs. In the experiments with Nick the neutral stimulus (light) ...y 5 seconds and then overlapped the primary cs (bell, tone). With ...ders, the neutral cs (light) should have become an inhibitory stimulus ...a stimulus of the second order. Whether or not this difference is ...ne for such a pathological pattern, or whether it is a special charac- Nick cannot be revealed by our data.

...somewhat similar situation to the normal one in which a neutral stim- ...transformed into a cs. Lindberg and Volborth (*104*) have shown that ...eutral stimulus is given even in the *same milieu* with an inhibitory ...the neutral stimulus acquires an inhibitory property though it does not ...time with another inhibitory cs; if it does coincide, however, its effect ...

...eed of elaboration and the amazing stability of the new pathological pat- ...the light in Nick illustrate clearly the mechanism by which abnormal ...such as phobias, anxiety states, etc., as well as prejudices, may be formed ...man being. Let any neutral stimulus, any perceptible change of the ...ent occur simultaneously with or even in the same milieu with an intense ...and this neutral stimulus will acquire the property of provoking the ...al pattern of reaction. Here the relation is even more accidental and less ...in the connection between cs and normal cr which must be based upon ...many combinations of the conditional signal and the inborn reflex action However in the pathologic state (Nick) a neutral signal coincided only a ...s with one of the generalized csi of the pathological behavior. Such a ...stimulus will itself evoke the same pathological pattern, in spite of the ...this neutral stimulus has never occurred with the original excitant nor ...the actual conflict, and may be removed even for several years.

...ase of formation of pathological crs compared with the normal may have ...in the type of expression: the specific movement or secretion is the usual ...nt recorded whereas in the pathological cr we are recording the emotional ...nts. That these latter may be more readily conditioned and longer re- ...has some experimental foundation, e.g., it has been recently shown in this ...tory that the cardiac component of a food cr can be retained to last two years

when the more specific secretory component has completely disappeared (experiments of Marion Lusky). Also Mumie and I have demonstrated that [illegible] patients with marked memory deficit lose the specific motor crs to [illegible] but retain the emotional expression (reluctance to enter the room, [illegible], etc.).

Thus the basis for forming the pathological patterns and prejudices seems in the susceptible animal to be more active and potent than are the normal unconditional excitations such as food and pain. By such a mechanism it is clear how illogical and accidental are the relationships between some of the excitants, e.g., for the [illegible] anxiety states or for our prejudices, based as they are on certain emotional [illegible]. The combination of the neutral agent may, as is seen in the above experiment and as is known to every clinical psychiatrist, have been so remote and accidental as to have been long forgotten. Apparent analogies are frequently risky. However the following human example is illustrative of how generalization may lead to unwarranted prejudices. A three year old normal child who was afraid of a certain man (without known reason) became frightened and started crying on seeing a picture in the newspaper of this man's cousin—not from the picture itself but when told it was a cousin of the man who was feared. Such prejudices are illogical in the sense that they may have no connection whatever with reality external to the organism; but they may be strictly logical from another point of view—they may constitute the subjective superstructure to the reality that is going on inside the organism, viz., the increased heart and respiratory rates as well as the other visceral components that have been demonstrated not only in emotions but as part and parcel of all the crs. (Gantt and Hoffmann [[illegible]], Gantt [[illegible]], W[illegible] [[illegible]]).

In the beginning of this section it was stated that the environmental [illegible], as well as a specific stimulus may become a powerful cs for the animal. Although it is the fashion to call the "whole" environment the stimulus this is not necessarily correct. The animal reacts to certain elements of the milieu and may neglect others. What the predominant stimuli are can be determined only by experimentation or observation—neither by guessing what we think is most important for the animal nor by assuming as we are often advised that the environment acts as an indivisible whole. On the other hand the organism fastens on certain of these elements and reacts to them; for example Nick giving sexual erections and ejaculation to the food used in the camera when this food was presented to him on the farm 200 miles from the laboratory environment, his sexual erections to the people who worked with him, his reacting to whistling and other similar auditory stimuli the same as he did to the tones.

In my article "The Role of the Isolated Conditioned Stimulus in the Integrated Response Pattern, and the Relation of Pattern Changes to Psychopathology" [[illegible]] I have attempted to point out why it is even more fallacious to speak of the "whole

...ment" than of only a single concrete cue as the main stimulus for the or... by leaning over backwards to avoid one pitfall the proponent of the ...often somersaults into the opposite pitfall, showing the danger of verbal ...ons without studying the facts in any given situation. ...al Correlations

...h it is not possible to diagnose Nick according to a clinical disease ...such exists in psychiatry—it is interesting to point out the analogy of ...ive symptoms. To do more than this at the present time is a thankless ...fitable task owing to the unsatisfactory basis of the present clinical clas... The unstable basis for classifying psychiatric conditions is shown by the ...often psychiatrists disagree in a large percent of diagnoses, or that the ...s changed during the course of the illness. For example the prolonged ...among eminent psychiatrists as to whether the depressive reactions occur...middle age form a separate group (involutional melancholia) or should be ...d as manic depressive; the classification of anxiety states as merergasias ...questioned recently by Leslie Hohman (56) who produces evidence ...are more properly milder degrees of pathological depression and elation. ...n, choking attempts to escape, and fearful-like timidity of the anxiety ...at be applied to Nick's behavior. But since in the patient the emphasis is ...tive symptoms and in the dog necessarily on the objective, a close com...becomes difficult.

...to the above considerations as well as to the wide variations from patient ...t, the thorough study of the individual and his particular reactions to life ..., i.e., the patterns of behavior and their origin is probably much more ...nt than the attempt to place him in a group of disease-entities.

...other obstacle to comparing the animal with the human patient rests upon ...nce in methods of examination. In the dog the only phenomena that can ...tively recorded and measured impress themselves upon us by certain ...gical observations plus the gross changes in behavior. In the patient the ...s is chiefly, though not altogether, made on the basis of the patient's sub...reports of what and how he feels, the sensory impressions as hallucinations, ...his ability to maintain a satisfactory rapport with his work and in his ...society. The data of clinical psychiatry are obtained almost exclusively ...h the medium of speech, while in the animal this is the one method by ...we obtain nothing.

...spite of these differences, certain resemblances seem warranted. The chronic, ...typed patterns of reaction in Nick are mainly evident in particular environ-

ments or occur to elements of this environment. Although measurements of ... 24 hour activity indicate that the effect of the environment may extend far beyond the period that the animal is actually there, the striking pathology is strictly environmentally determined. Further proof of this is the benefit when removed from the environment, and conversely the possibility of forming new pathological stimuli in the given environment.

The stereotyped pattern of Nick's behavior and certain adventitious actions were as prominent as any seen in patients. Besides those disturbing reactions connected with the conflict of the camera was the playful attitude toward the food used in the experiments (Spratts ovals) outside the camera—picking them up, fumbling them, or running around the room with them in his mouth, then dropping them, and rolling them on the floor with his paws. Another marked symptom was his extreme hyperactivity especially in the experimental environment, his stereotyped jumping off and on the stand in the camera.[20] Negativism toward the people who worked with him continued for years.

Such negativism, a prominent symptom in Nick, has been reported in many of Pavlov's dogs. Thus in his animals during the hypnotic phase, the dog stubbornly turns away from the food but attempts to get it as we remove it.[21]

The stereotypy, playfulness, incontinence and negativism are prominent symptoms of schizophrenia, but the fact that these phenomena in Nick were confined to the environment or its elements of the conflict and that his total behavior was not predominantly disturbed were objections to considering him a schizophrenic.

Very prominent and persistent among the abnormal symptoms was the orientation of Nick toward the former location of the pathological tone, and not toward the new position given it about 1935—after the period of acute stress. This orientation consisted in turning his body, gazing at a spot and backing away from it (see frontispiece and fig. 39). The failure of Nick to react to reality in the present, but to a pathological stimulus of the past is a constant and immutable symptom which has lasted for over 7 years, and appeared with clock-like regularity. This orientation to the past is in fact no more significant than the spontaneous transformation of Nick's food crs to defense reactions, but it is more striking, in

[20] Pavlov has observed in his disturbed animals symptoms of stereotypy, e.g., constantly repeated ... longed licking of certain objects. Many other movements may become stereotyped in the patholo... animal. (*89*, pp. 40-41).

[21] Pavlov, though usually remaining objective, contrary to his principles indulged in the follow... subjective explanation: "One can conceive in all likelihood that, if these dogs which have becom... could look back and tell what they had experienced on that occasion, they would not add a sing... to that which one would conjecture about their condition. All would declare that on every one of ... occasions mentioned they were put through a difficult test, a hard situation. Some would report that ... doing it in one way or another, while others would say that they were totally, or just passively, unable to do what they usually had to do" (*89*, p. 84).

...it does vigorous and stereotyped movements away from a specific place ...

...sidered such an action an obsession. He describes a dog in whom a ...verse reaction persisted 18 months after the stimulus had been replaced ...other position—but in Nick the same pathological reaction persisted ... Pavlov says: "Other conditioned stimuli were located in various other ... when they were put into action the dog still preferred to turn towards ...ere the noise had been produced. . . . On the application of any other ...inating in quite a different place the movement of the dog was always ...the place where the noise had formerly been heard. . . . Towards the ...terval between the conditional stimuli, i.e., before the beginning of ...mulus, dogs often get into a state of "food excitation" (time reflex), ...ng towards the food-box, or to the place of one or the other conditioned ... The above-described animal turns only towards the place from which, ..., the noise had been heard" (*89*).

...scription of Pavlov's animal could be applied almost verbatim to Nick.[22] ...action of Nick's suggestive of compulsive behavior was the stereotyped ...ch after the neurosis he picked up the food, ran about the room with it, ..., rolled it on the floor and played with it, though he would not eat it. ...f the other symptoms were expressions of pathological functioning of ...omic nervous system—in the respiratory, cardiac, gastro-intestinal, ...nd sexual systems.

...riking and stereotyped manner in which these various symptoms ap- ...er a period of 8 years in Nick, and the apparent lack of marked inter- ...th his life outside the laboratory would place him in the category of ...ents showing patterns of dysfunction in the autonomic nervous system ...aracterize the anxiety states,[23] though it is true the extreme hyperactivity ...fulness in the environment are symptoms seen in the manic.

... Cobb,[24] in summarizing the symptoms of 100 patients with what he ...call anxiety attacks rather than neuroses, lists the following manifesta- ... their frequency: *palpitation* 96%; *attacks in a special setting*; *fear* 90%; ...fficulties 88%; *dyspnea* (smothering) 85%; *trembling* 75%; *sweating*; ... 98%; irritability 90%; chest oppression 70%; dizzy, chills, pain 60%; ... 25%. These symptoms he states also characterize neurocirculatory asthe- ... Army. There is a striking parallel between the objective signs in Cobb's

... read at the Association for Research in Psychoanalysis and Experimental Psychodynamics, ..., 1942.

patients (italics above) and those of Nick; since the other symptoms depend upon the report of the patient no comparison can be drawn. Every somatic manifestation of Cobb's series is a marked symptom in Nick.

Furthermore the respiratory changes in Cobb's patients bear a close resemblance to those of Nick. Cobb noted respiratory anomalies that are closely comparable to the 1st (rapid panting) and 4th types (quiet, after petting and sexual excitation) of respiration in Nick, and another kind in patients having qualities of the 2nd and 3rd types in Nick. The very rapid breathing of Cobb's patients during Army inspection or when they thought of something unpleasant was similar to the panting of Nick, and the slow regular breathing of a patient when he recalled a fishing trip and vacation (even slower than his relaxed breathing) was almost exactly similar to that of Nick when he was being fed or during the last stage of sexual stimulation.

The impotence and sexual difficulties described by Cobb also find a parallel in the suppression of the sexual reflexes in Nick in the environment of conflict. The sinus arrhythmia, present in 96% of Cobb's patients, was a striking symptom from the very beginning of Nick's disturbance, not only to the environment but to all its elements and even to the people connected with it. Moreover the heart rate varied in Nick according to the person who was taking it, an observation which would be interesting to confirm in patients.

If Nick had been a patient he would undoubtedly have been treated for anxiety attacks and been labelled with the terms merergasia, phobias, gastric neurosis, functional tachycardia, asthma, enuresis, ejaculatio praecox, etc.

THE FACT that in clinical psychiatry, drugs, except for the possible ... used in shock therapy, have had only an ameliorative effect, and ... such sedatives as bromides has been thoroughly studied by Pavlov, ... others, a thorough study of the pharmacological treatment of the ... neuroses has not been carried out here.

... showed that bromides had a beneficial effect on the experimental neuroses in dogs of a certain type, and that the dose should be accurately regulated in accordance with the type—for the strong type 5 to 8 times greater than for the weak type. Its effect is the reinforcing of the inhibitory function particularly ... and unbalanced types (*89*).

... has confirmed Pavlov's findings with bromides in dogs. However he ... even hyperactive cats do not respond to bromides favorably, and he ... that this drug must be carefully selected in reference to both the species ... of neurosis. (Personal communication of unpublished data).

... forms of therapy however warrant attention here. As cortin had been ... of value in anxiety states (Thorn [*54*]) and as Liddell (*71*) had found ... diminished motor hyperactivity in the sheep, this drug was given to Nick ... weeks in 1934, however, without benefit, as mentioned in Nick's his-

... (personal communication) has suggested that alcohol might relieve ... the experimental neuroses. Experiments in several dogs indicate that ... in temporary effects in this direction, which do not continue however ... some days (rarely longer) after the administration, i.e., the relief is ... ent. In one of our dogs, Blue, who was a shy, sensitive, somewhat in... type, the use of alcohol on several occasions made him more normal the ... in his relation to other dogs, with the result that he defended himself ... aggression instead of running away.

... was given to Nick in May, June and July, 1938, and also in April, May ... 1939, chiefly for the study of the effect upon the sexual reflexes. As in ..., alcohol had a delayed effect on the onset of ejaculation and a short... the period of erection in small doses (1 cc./kgm.) and in larger doses ... completely inhibited the appearance of the sexual reflexes. With 1 ... alcohol the latent period of the onset of erection increased from 30″

... has recently shown that alcohol has a marked analgesic effect on physical pain. It ... the mood, and from previous work it is known that it lessens tension between excitation ... by impairing differentiation.

(control) to 35″ (alcohol) and the duration of erection decreased from 11½ minutes (control) to 6.7 minutes (alcohol). Since the camera itself had a tendency in Nick to produce ejaculatio praecox, the use of small doses of alcohol may be used to correct this, though at the same time diminishing by one half the duration of erection. However, the high control figures, taken on alternate days to the alcohol, which was given two or three times a week, apparently resulted from the use of alcohol on the previous day, as they were never so high before as during the period of alcohol administration. This remarkable and unusual effect obtained in Nick on the days following alcohol administration showed that the sexual erections to adequate stimuli were increased from the normal average of about 3 minutes to an average of about 12 minutes after a single large dose of alcohol on 17 May, 1938. This effect lasted until 22 June, 1938, as shown in fig. 48.

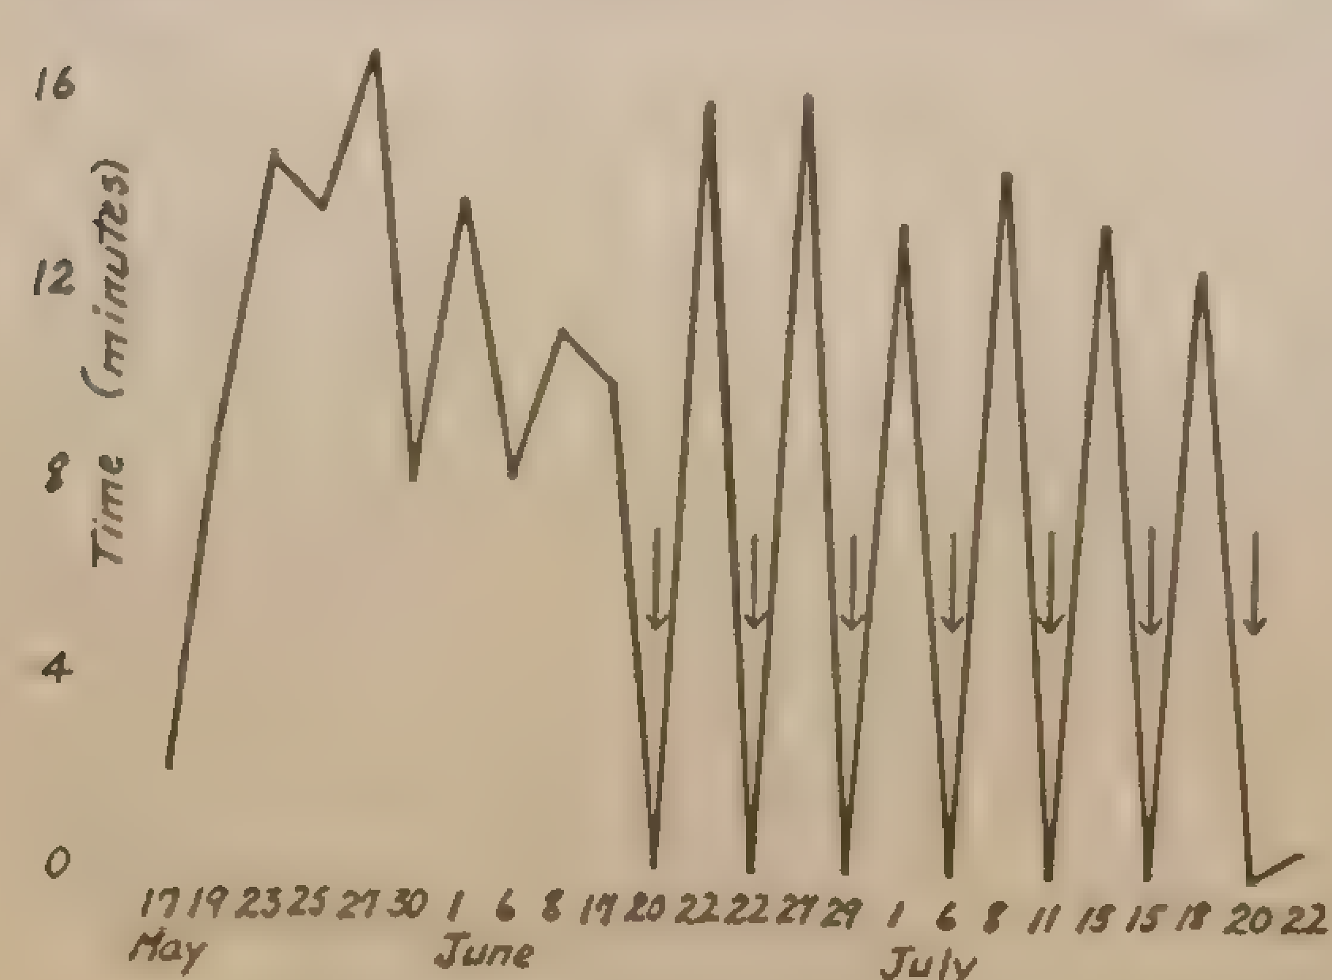

FIG. 48. Effect of alcohol on duration of sexual erection in Nick. Administration of alcohol indicated by arrows.

The alcohol not only completely removed the inhibitory effect of the camera on the sexual reflexes but resulted in their being much larger even in this location than they ever were elsewhere. It was also noted that Nick was very much quieter in the camera after this dose of alcohol (2 cc./kgm.). The tone or bell continued to have a slight inhibitory effect on the sexual erections. The large dose (2 cc. kgm.) was repeated on 20 June, 1938, and though the sexual reflexes were completely abolished on that day, they showed a new peak on 22 June inside the camera and even in the presence of the tone. Fig. 49 shows how the sexual reflexes continued strong for the next few months.

Beginning on 29 March, 1939, small doses of alcohol were used and on the alternate days sexual reflexes were again markedly increased.

With yet smaller doses of alcohol on Nick (0.5 cc. kgm.) there was very little effect on the sexual reflexes.

The effect of alcohol on the sexual reflexes in a series of normal dogs is as follows: with small doses (½ cc./kgm.) there was only slight change but with moderate doses (1 cc./kgm.) the latent period was prolonged somewhat and the duration of erection markedly shortened. With large doses (2 cc./kgm.) the sexual reflexes to adequate stimuli were completely abolished. The alcohol was given in a 20% solution orally on an empty stomach. Even with small doses the alcohol did not have any stimulating influence (fig. 49), the *increase* of latent period of

ferentiating ability to return slowly following the cessation of the convulsions (figs. 3a and 3b).

Persistent efforts were made to transform Nick's attitude towards the experimental environment by influencing this through the change of tension in the food excitation. As starvation for 48 instead of 24 hours stimulated him to enter the camera more readily and lessened the defense reactions somewhat, an attempt was made to transform the experimental environment from a painful to a pleasant one by giving him his daily ration of meat there and only there for several months in 1936. Except for the fact that he did accept his food in the camera and he seemed a little quieter during these months, no permanent effect was obtained.

Another later procedure which gives more therapeutic promise is the connection of the csi (originally associated with food and later evoking conflict) with a new UR excitation (drive). In March 1942, as described in his history, an attempt to form out of the old csi new ones for a definite motor defense reflex, has resulted in Nick's not only being able to form these new motor crs out of the old csi for anxiety, but in a marked reduction of the restlessness and agitation. A comparison of the respiration on 18 March, 1942, (fig. 50), with that of a year ago (figs. 25 and 26) in the same camera shows how much less active he is in the new situation.

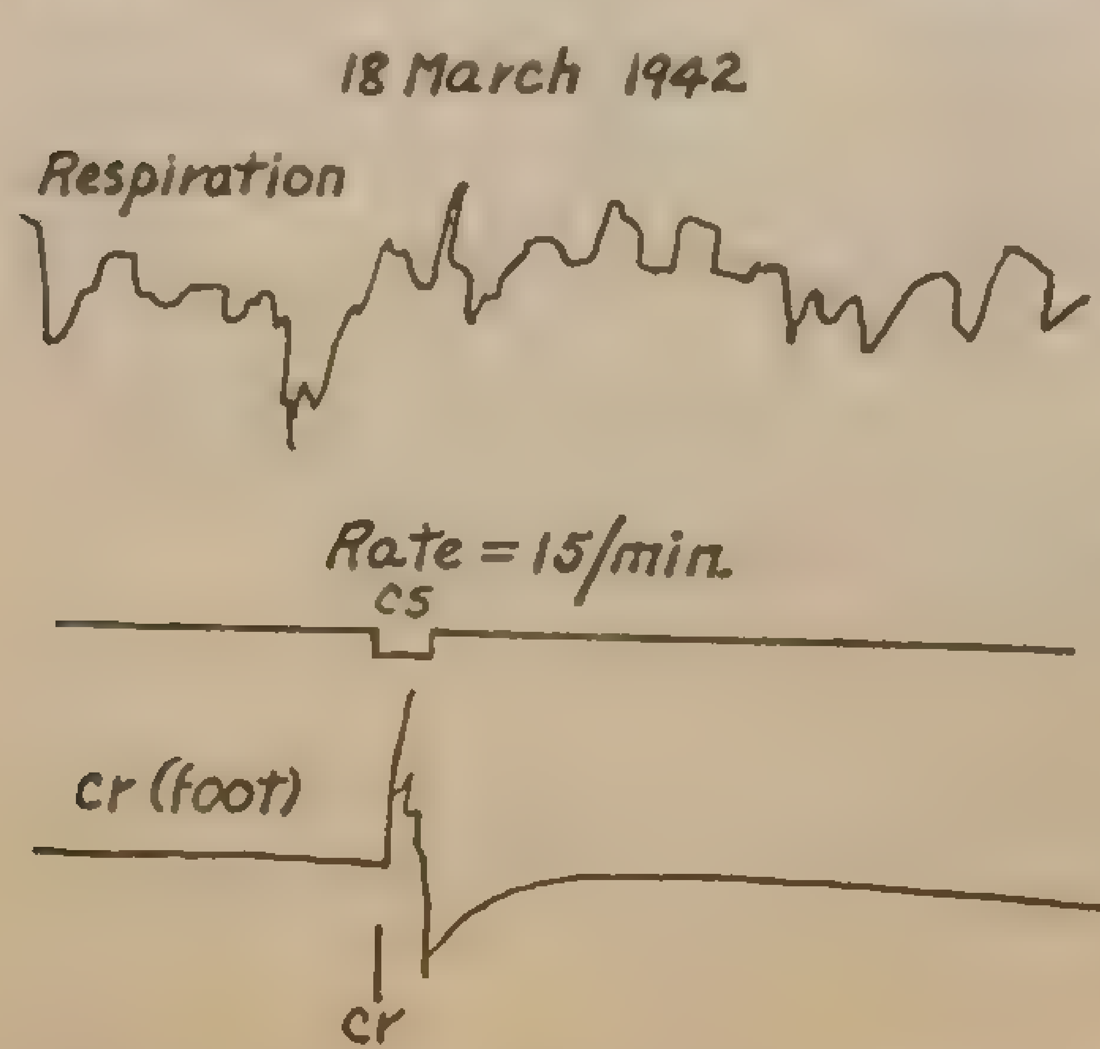

FIG. 50. Quieter respiration in Nick accompanying new cr formation. Cf. with figs. 11, 28, 30.

It is too early to speculate on how permanent this form of therapy will prove to be, but at present the pathologic effect of the old csi (connected originally with the food, later with defense, and then converted into csi for a pain stimulus) seems to have disappeared for the first time since it began in 1932. The change in his behavior is so striking that I feel warranted in mentioning it here in spite of the shortness of the period during which the animal has been subjected to the new experiments, and the question as to whether other factors, e.g., increasing age, may have contributed.

There is a temptation here to make a comparison with the stimulating effect of War. In its initial phases, until disillusionment, extreme fatigue and exhaustion set in, there is an exhilaration throughout society which more than counterbalances the discomforts and privations. This stimulation is not only seen in normal people, but in the lowered suicide rates (in almost all countries, e.g., in Russia [32, 35] and now in this country), and in the decreased number of neuroses in the hospitals.

...ll recall here that Pavlov's experiments using food and defense ...y resulted subsequently in a nervous breakdown and that when we ...flicting csi (1934) as new csi for another defense UR (injection ...e mouth) Nick formed the new cr but did not show any permanent ... ...revious section (Ch. IV) it was pointed out that the US (which fol... ...cr) inhibits all the previous specific cr activity and provides the animal ...escent period during which it is freed from the stimulation of the same ...d csi. Sexual excitation was for Nick, and for many dogs, much stronger ...fied excitation. Thus it provides not only a resting period from stimula-

tion by agents specific for itself, but also by pathological agents related to the nervous disturbance. Such a mechanism however, holds good only for short periods, some minutes. (This discussion, dealing here with only an acute mechanism, should not be interpreted as operative in human behavior, except as a very limited physiological mechanism, which neglects consideration of all the social conflicts that may arise directly or indirectly on the basis of sexual excitations.)

Acting upon the suggestion of several psychiatrists who had seen Nick (Kazanin, Murray, Saul and Whitehorn) and my own previous observations of the effect of the presence of a human companion, Nick was transferred to my farm in Virginia for two periods, two months in 1937 and 18 months later (1938 to 1940). Not only did this involve a complete change of environment, except for the months when he saw me, but he also had an opportunity to develop new relationships toward me.

As the change of environment involved new as well as changed personal relationships it is impossible to say from which of these factors most benefit was derived.

The first period on the farm was from 1 August, 1937, to 3 October, 1937. His initial negative attitude toward me on arriving has been mentioned. In a few days he became friendly, barking and jumping up on me when I approached him. During the first days there he would not eat the Spratts ovals (fig. 23), though later on he did; there was at that time pollakiuria as well as a peculiar pattern of defecation with erections and growling and scratching like a cat with all fours—also seen in normal dogs when sexually excited.

On returning the dog to the laboratory on 5 October, he ran and jumped up on the stand in the camera, there was no urination nor whining, nor fawning nor panting. This improvement lasted for two or three weeks, after which he gradually returned to his former state; the respiration became more rapid with whining to the tone backing off from its former location; sexual erections began to recur in the camera. The improvement is evident in the comparison of figs. 10 and 11.

The second period of rest in the country lasted from 26 August, 1939, until 11 January, 1941. The quieting effect of the change was immediately reflected in the cardiac rate, which was 200 in the antecamera the day of his departure from Baltimore and two days later on the farm only 110. But the other symptoms disappeared only by degrees.

While on the farm he gradually became quieter and in time nearly all the symptoms vanished for the most part though they recurred at irregular intervals especially when he was presented with any element of the laboratory environment. His chaotic reaction toward these has already been described, viz., to the Spratts ovals—negativism, urination, and occasionally erection; to my approach—often agitation, sometimes urination, or erection with ejaculation.

summer of 1940 I made a definite effort to become friendly with him, taking him with me on walks and in the automobile. The ...nships produced a marked effect. Heretofore he could never be ...the dwelling without extreme agitation accompanied by micturition, ...ing, etc. But after my close association with him he became a most ...anion, following me everywhere, even into the river at about age of ...had never learned to swim before. He exhibited toward me more ...ffection than pet dogs which I had there at the same time. As a result ...hen brought into the dwelling he would, in marked contrast to his ...avior, lie down quietly at my feet for as long as 45 minutes, without ...turition, panting or any sign of the previous disturbed behavior.

...pparent to all those who had known Nick that his behavior was much ...ormal that it had ever been since the beginning of the disturbance in

...returned to the laboratory in 1941 he remained improved for several ...and is still not quite so disturbed as he was previous to his prolonged rest ...untry. The benefit was reflected in his quieter behavior toward me, the ...d agitation, and the fact that the experimental environment had not the ...nhibiting effect on the sexual reflexes. However, sexual erections still ...d when he was taken into the camera. Although his general behavior was ...disturbed as formerly, there were days during which his rapid respiration

and other symptoms showed that he was by no means cured. His improvement can clearly be seen by comparing the respiration on 27 February, 1941 (fig. 25) with that in 1937; the heart rate before being taken to the country, while there, and on his return in 1941; the effect of the camera on the sexual reflexes as shown in fig. 40. That the old environment had an effect on him can be seen by comparing the heart rates in the camera (rate = 117) with a room in the laboratory where Nick had not previously been (rate = 90, fig. 51).

Of all the therapeutic measures employed, the prolonged rest in *another environment plus the social factors* were almost the only ones effective, except for the new procedure of transforming the csi mentioned above. While on the farm he was apparently all but cured. But when brought back to the laboratory life the gradual reappearance of his symptoms indicated that the cure could not survive a return to the old environment.[3]

The pronounced influence of the social factor in maintaining normal life is evident especially in the dog (particularly his relation to the human companion) but also in many other species. In Chapter III several instances were mentioned of how dogs became depressed, or even die after the death of their masters. And even in an animal so far removed from us as the bee the deprivation of the society of its fellows, even though all the other living conditions are maintained, results in the failure to take food and death within a few days.[4]

The social factor is now recognized among the representatives of psychosomatic medicine and others as extremely important. Just as it has been shown that the heart rate of Nick varies with the person who is taking it or standing by him, it has been suggested that one of the elements from which improvement from shock therapy results is the added attention that the patient gets. As Whitehorn points out the percentage of cures of patients receiving shock therapy in State hospitals is approximately equivalent to the percentage cured in a private sanitarium without shock therapy.

[3] Dr. Catherine Stuber and Henrietta Brady have reported a rapid and marked improvement in many schizophrenics transferred from the state Hospital to farmlife.

[4] Maeterlinck, Life of the Bee, N.Y. 1901. "Isolate her [the honey bee], and however abundant the food or favorable the temperature, she will expire in a few days not of hunger or cold but of loneliness. From the crowd, from the city, she derives an invisible aliment that is as necessary to her as honey."

## INDIVIDUAL VARIATIONS AND REACTION ... IN DOGS[1]

...ently two compendious works have been offered with the purpose of com... the study of external configuration and function. One of these is the work ...ckard which has been extended by Liddell's co-workers (Anderson and ... ...2). The other is the comprehensive system of Sheldon (100, 101) based

[1] ...pt is made here to review the different systems of constitutional classification. Of the recent ... ...der is referred to Sheldon's detailed and painstaking work embodied in *The Varieties of* ... (N.Y. 1940) and *The Varieties of Temperament* (N.Y. 1942) for a description of ... of configurational classification; and to the excellent and well balanced review of Barbara ... ...ing the various systems of classification (6).

upon thorough and detailed measurements. While neither of these offers a final answer to the question of constitution they give a rational basis upon which the facts may be tested.

In a general sense, there is no denying the relation between structure and function. "Just as it is written in the tongue, the stomach, and mouth of the bee that it must make honey so is it written in our eyes, our ears, our nerves, our marrow, in every convolution of our brain, that we must make cerebral substance; nor is there need that we should divine the purpose this substance shall serve" ([illegible]).

The nature of the executor reaction is of little importance, for the connections are made in the central nervous system, and the effector organ may produce very divergent results, not necessarily because the central connections are dissimilar, but because of the executors. Owing to the varying structures of the external defense organs, what a vast difference there is between the reactions to an enemy of an electric eel, a serpent, and a tiger. Each performs like a puppet pulled by strings, depending upon what the string is attached to; according to whether the executor is an electric battery, a sac of venom, or teeth and claws (*31*).

In spite of the value of the theory of constitution plus environment in shifting from an exaggerated emphasis on the details of cellular and microbic pathology (Virchow) to a consideration of the whole personality, there are two serious objections to most types of classification. The first is the selection of a characteristic that has a constantly high correlation with the function in which we are interested. The second is the delimitation of the groups—the *raison d'etre* for a decision as to what constitutes the dividing line between groups.

Some of all these physical measurements may be correlated with functional ability but often the correlation is too small to have significance for any accurate prediction. Even so intimate and seemingly pertinent a correlation as brain weight and intelligence is not always paramount, e.g., Anatole France with his very small brain.

Variations from one individual to the other may be greater within the same breed (of dog) or race than are the differences between the individuals of separate breeds or races.

As regards races and structure:

In the past two decades a number of anthropologists have maintained from numerous measurements of the intracranial capacities of many different races of mankind that the different races probably have about equal average size of brains hence equal potentialities for intellectual development if given sufficient proper cultural stimulation for a number of generations.

The assumption, common to this group of anthropologists (Ashley-Montague, 1940) is that the characteristic physical differences in such organs as the skin, hair, nose, eyes, teeth, cheek bones, and size of body, are superficial differences which have nothing to do with the

... capacity for developing intelligence. This assumption neglects the fact that ... receptors and cortex, and not shape of organs, is indispensable for developing ... Neurologists have recently found that intracranial measurements and phreno... are, after certain basic dimensions are fulfilled, unreliable indicators of the ... developing intelligence. Relatively small brains have been found in men of great ... brains in men of low intelligence. (Kempf, unpublished MS on Attitude.)

...ing of hard and fast lines between groups often means that the individ... be forced into a Procrustean mold. And what should be done with the ...ates? Or he may fall into one category in one system and into an oppos... by another system.

...ystem depends in its final justification on the correlation of the charac... chosen as the index to particular *functions.* It is eventually the function ... the physical characteristic in which we are interested. If there is a justifica... the classification of types, temperaments, or constitutions, a study of the ... *of individuals under similar circumstances* furnishes a reasonable basis ...gh classification. The search for the most *significant* factors rather than ...ments which may (or may not) have a correlation with function should be ... As the physical type is used to predict function, is it not better to *measure* ... directly where this is possible rather than by the indirect method of cor... of physical structure with function, just as it is more important to be ...ted with psychopathic function than with psychopathic anatomy. ...le any information that can be derived from all the intricate anatomical, ...al, racial and social groupings should certainly not be neglected, the study ... individual for himself is the most direct approach and involves the most ...nt items. Perhaps such a carefully compounded structural system as that ...don (100) may through its comprehensive and careful description of struc... factors give a basis for more exact correlations than were formerly possible. ... spite of what we may learn from structure, it is function rather than struc... that ultimately concerns us, and therefore the function of the individual is ... criterion. Adolf Meyer has been one of the chief exponents of the study ... function of the individual (ergasia), laying emphasis on the behavior of the ...dual in his life experiences. This behavior is an essential element in both the ...lity and the psychopathology of the individual, and the importance of ... systems is only for the light they may throw on this central question.

...tional grouping has the advantage of placing the emphasis upon what is ... important in the study of nervous disturbances—and that is how the individ... behaves in a given environment and whether his reactions (pathological, as

well as physiological) in a selected environment reveal anything of his suscep-
tibility when confronted by a situation of especial stress or conflict.

Although a study of function may seem less objective and more variable, this is hardly true if the conditions are kept constant; and it is function with which all other group characteristics must be correlated to be significant. The constancy of the measures of function has been referred to (see fig. 4), and throughout the book as well as in everyday experience there is evidence that function may change without discernible abnormalities in structure.

When the difficulty of a satisfactory external classification is so great the question arises: Is it not simpler to place the emphasis on the study and classification of function itself where this is possible?

Before describing my own results, I summarize below the classification of Pavlov, based on function and much closer to the ancient Hippocratic one of temperaments than to the anatomical groupings.

In a study of hundreds of dogs Pavlov noted certain functional types. In 1925 in Paris he described the "inhibitory type," a type in which the negative crs predominate. These were usually timid, cowardly animals who moved cautiously with tucked tail and bent legs. In contrast to this was the lively, excitatory type who was always alert and active, and in whom the positive crs overbalanced the inhibitory. However this lively type when restricted becomes easily inhibited and paradoxically is the first to fall asleep or into pathological states under the experimental restrictions. In 1927 Pavlov (88) classified his animals into three chief groups: an excitatory, an inhibitory (extreme groups) and a central, well equilibrated group. He furthermore referred his groups to the classical temperaments of Hippocrates, the extremes representing the choleric and the melancholic, and the normal central group the sanguine and phlegmatic. "The characteristic differences become exaggerated under the influence of various prolonged nervous disturbances which develop as a result of excessively strong stimulation or of unresolvable conflict between the two nervous processes (excitation and inhibition)."

Our investigations of the susceptibility of certain dogs to nervous breakdown has been made insofar as possible from the point of view of the study of the individual for himself rather than as a member of a group. There are certain modifications necessary on account of the difference between dog and man, the most important of which is perhaps the presence of speech function and the correlated symbolization in man. With the human subject it is often possible to evaluate the preliminary conflicts from a subjective account based on language. Thus we may obtain his own inner elaborations and the more intricate reactions to life experiences. With the animal as well as with some patients we are cut off from this avenue of approach and the studies must be wholly independent of all those verbal feelings of what the subject is thinking about, how he relates an episode to us, and

[illegible] ourselves with how he *acts*—with measurable items, the evidence [illegible] and inhibition (positive and negative conditional responses), as mea[illegible] the motor system and the autonomic responses (cardiac, respiratory, [illegible] muscular activity, the ordinary observable behavior—and then com[illegible] behavior with what we see and know in the accessible human being.

[illegible] with its disadvantages and advantages. If we are unable by the method [illegible] to delve into the dog's past, as well as that of some patients, we are, on [illegible] hand, free of the subjective interpretations which enter more readily into [illegible] into less personal and more definitive records, and we get a record [illegible] comparable from one period to another, or from one individual to another.

[illegible] the most significant and impressive facts that has come out of the mate[illegible] study of animals subjected to nervous breakdown is the variation in [illegible] of individuals. A reference to the parallel life summaries of the three [illegible], Peter and Nick illustrate how the result depends even more upon the [illegible] than upon the environment when we consider it from the point of [illegible] life history and not simply the acute effects of the daily routine. Parallel [illegible] have been undertaken with other dogs with the same results, viz., the [illegible] showed only a slight or temporary disturbance, the susceptible a pronounced [illegible] chronic neurosis.

[illegible] most important factor in relating personality to instability is the observa[illegible] of the animal under conditions of imposed stress, as has been fully described [illegible]. The importance of the individual can be seen from a comparison of [illegible] Peter and Nick. Figs. 8 and 39, 21 and 22 picture the different attitude of [illegible] put through the same procedure.

[illegible] order to study the susceptibility of the individual I have made use of two [illegible] of information; first, observation of all the natural viscissitudes in the ani[illegible] and environment such as is outlined in the dynamic life chart of Adolf [illegible]; second, placing the animal in a position of natural or *artificial stress* or [illegible] and noting his reaction and susceptibility measured in as many physiologi[illegible] systems as possible.

In addition to the balance between positive and negative salivary crs as measured [illegible] Pavlov, the study of our dogs has been extended to include a variety of obser[illegible] taken over a major part of the life of each animal. Among these are the [illegible] activity (a record of the running movements); the character of the [illegible] variations (respiratory, cardiac, sexual) and their cr rates; the suscepti[illegible] to drugs such as alcohol; the adaptability to a change in routine; the regu[illegible] of the cr and UR records; the social, both human and canine, adjustments; [illegible] variability in the performance of the animals from day to day as well as under [illegible] conditions of stress.

[illegible] this point of view has gained ground in psychiatry (see Whitehorn *107*).

In the dogs which we have studied two striking facts emerge: first, the pattern of breakdown in a given individual remains relatively constant, and second the pathological disturbances are expressed in many systems, e.g., a loss of differentiation in the food crs may be accompanied by chaotic relations in respiration, in the pulse rates, and in the secretions (drop of the food crs to zero), and in the suppression of sexual reflexes. (See Ch. VI.)

The absolute amount of the 24 hour *activity* is of no significance in the stability of the animal. Thus two of our most stable animals, as well as two of the most labile, showed extremes of activity: Billy, who has been mentioned elsewhere in this monograph, having an average activity equal to that of Nick, the extremely agitated and disturbed dog; while another dog, Brenda, had the lowest activity of any measured, lying in one place without moving for several weeks. However, there are other aspects of the activity which seem to have a bearing on a neurotic constitution. The fluctuations in the activity, though of some importance in separating active from quiet dogs, do not necessarily indicate labileness.

The most significant fact is that Nick and other neurotic dogs do not show a positive correlation in their activity with the normal dog. Apparently the activity of the two groups is affected by different factors or the same factors in different degrees.

In a previous chapter the effect of *natural emotional shocks*, such as that which occurred when our dogs escaped from the paddocks, has been described. It was pointed out that both the behavior and the crs (as a result of the shock referred to) showed the greatest changes in the most labile dogs. The fluctuation of the crs in the stable animal Billy compared with an hyperexcitable one (Kompa) and a phlegmatic one (Blue) are seen in fig. 6a.

A year later a parallel contrast was seen in a serious battle which occurred between the stable animal Billy and the labile one, Kompa (see fig. 6b).

It is of interest that the *excitatory crs vary* in their stability in dogs of different natures. Thus in Kompa the excitatory crs were less affected than the inhibitory; in a slight conflict they might even be increased. But in Blue, a dog of the inhibitory type (i.e., predominance of the inhibitory crs under normal conditions) excitation was more labile than inhibition. Compare for example the effect of the same situation on the two types of crs on Kompa and Blue (figs. 6a and b).

*Susceptibility to alcohol* was seen to be greater in Kompa, Nick and No. 3 (an animal with an organic brain lesion) than in Billy (30).

Also an *adaptation* to a modification in the routine of the experiments was best made by Billy, but poorly accomplished by Kompa and No. 3. Billy formed accurate crs to the sequence of the csi, i.e., the order in which the csi were given, as well as to the individual stimuli, while Kompa and No. 3 made the adaptations t

[illegible] very poorly, though they formed the crs to the specific csi independent [illegible] order.

[illegible] pathological phenomena show more *variation* than do the normal, e.g., [illegible] reports an increased variation in diameter of red blood cells after [illegible] and in pernicious anemia. The extreme variability of Nick compared [illegible] dogs is similarly suggestive of pathogenicity. Not only in his running [illegible] but in the heart rate, respiration, blood sugar, and sexual reflexes the [illegible] of variation is high.

[illegible] of variability may be a measure of temperament as well as of [illegible]. Therefore it cannot be assumed that any wide swing necessarily [illegible] pathological behavior; but the pronounced variability of Nick in many [illegible] gives a picture of an animal under constant bombardment of extreme [illegible] in every measured function. Even the stereotyped behavior of Nick [illegible] environment of conflict, though stereotyped, is a wide variation from his [illegible] function under other circumstances.

[illegible] important information can be obtained by subjecting the animal to a [illegible] and recording the effect on the crs; for the imbalance between [illegible] and negative crs is the first evidence of the failure of adaptation. The [illegible] artificial stress is the conflict between excitation and inhibition, [illegible] provided by the difficult differentiation of the csi. This test, furthermore, [illegible] the advantages of a very delicate measure for imbalance, shown by [illegible] in the magnitude and other relations between the artificial positive [illegible] negative crs. Moreover the disturbance can be observed and recorded long [illegible] there is an objective perceptible change in the ordinary behavior no matter [illegible] carefully observed. The imbalance is measured not only in the secretory [illegible] but in other accompanying autonomic components of the cr, e.g., respi[illegible] and pulse rate. Sometimes the disturbance is only an acute one, lasting for [illegible] minutes or several days. Examples of a beginning breakdown follow; in two [illegible] dogs, Kompa and Peik, the inhibitory effect of a new and poorly differen[illegible] such as a light, has been previously pointed out (Ch. IV). Both these [illegible] though of the excitatory type, showed a tendency to fall asleep. After the [illegible] had been used for several days in Peik, its effect was seen in the mounting [illegible] and *retardation* of movement, *cardio-respiratory* disturbances, inhibition [illegible] and of *abnormal sexual* reflexes. Then there were certain motor phe[illegible]—crouching, muscular inertness, refusal of food. The animal showed [illegible] drowsiness; the cardio-respiratory crs became disorganized. Thus, though [illegible] had been an increase in cardiac and respiratory rates to the csi, the disturbance [illegible] a new cs (light) results in a marked slowing of the heart and of respira[illegible]. The effect of the light on Peik is also shown in the cardiac rates—on 10

February the control rate was 90, the cardiac cr to Bu = 108 and the rate to L40 = 66; the respiration was increased with Bu but slowed with L40. (Experiments of Victor Rosen.)

The sexual reflexes were also inhibited for several days while the new disc was being used. This acute effect on the sexual reflexes in Peik was similar to the chronic manifestations in Nick. (See discussion of Sexual Reflexes, Ch. VI, section 6.)

As soon as the disc was removed from Peik's face he accepted food readily even while he was on the stand, and outside the camera he immediately ate voraciously. The removal of the salivary disc abolished the inhibition just as it often did in Nick; the effect is probably comparable to the removal of the hypnotic state by some small change of routine in Pavlov's experiments.

The correlation (negative) between stability and fluctuation was also seen in the UR secretion of dogs to a given amount of food (54). All the stable animals gave a constant secretion to a given weight and kind of food but the pathological dogs showed marked deviations.

Another example of the factors of instability not determinable except by the method of putting the animal under stress and then measuring the crs and accompanying reactions can be seen in the following two dogs, brought into the laboratory in cages. By casual observation of the animals running about freely it was not possible to get a consensus of opinion from eminently trained clinicians (both medical and psychiatric) as to which one would be more susceptible, though it was evident that C was the more quiet. However, when both were confronted with the same laboratory procedure of forming positive and negative motor crs to a faradic shock, C formed them more readily, differentiation quicker and there was less disturbance in his respiration, heart rate, and activity (figs. 26, 37, 52).

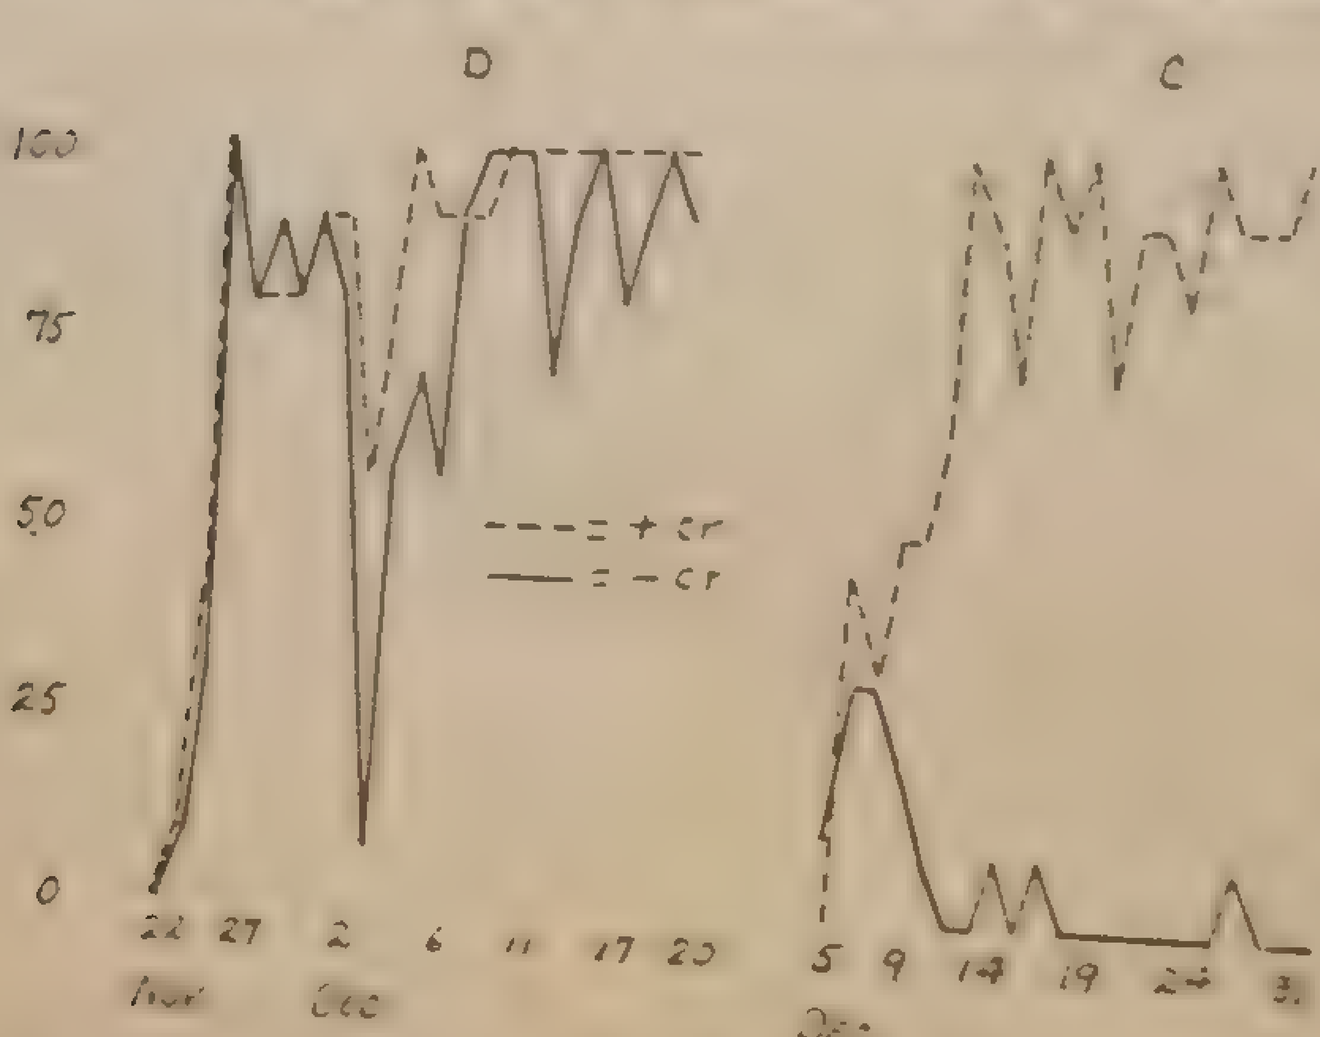

FIG. 52. [illegible] positive and negative [illegible] (D) and [illegible] (C) showing degree of differentiation between M[illegible] (+) and M[illegible] (−). Partial differentiation [illegible]

The hyperactivity of D compared with the more regular and placid behavior of C has been seen throughout in the cardio-respiratory crs as well as in the 24-hour activity record. Thus at the end of November before the two dogs had

...ed between two metronomes (M60 and M100) one of which was ... a faradic shock, the pulse rate was markedly increased in D, but only ...nged (decreased) in C (Table 29). On December 11 the deviation ...ed in both dogs, and at this time dog C showed a differentiation both ...nts and in the heart rates, but D showed no differentiation.

...ry 3, 1941, dog C was differentiating between M80 (+) and M100 ...fully avoiding the shock, and the heart rates with the csi were 68 ...ctively, compared with 76 control. In dog D the cr heart rates were ...19 respectively, compared with control of 85. However when this dog, ...duction of a new differentiation, could not avoid the shock, the heart ... conditioned long before the proper muscular movement, showing an ...ate of 150 compared with 113 in the control intervals.

TABLE 29

CONDITIONAL HEART RATES IN STABLE DOG (C) AND IN LABILE DOG (D)

| [illegible] | CONTROL | HEART RATE | | | |

...ther or not the fluctuations are another measure of the same thing that the ...l behavior is, the existence of the fluctuations in so many systems in ...le animals and their absence in the stable ones seems more than a coinci-...

...dogs can be put into one of the four Pavlovian groups of temperament, ... the most evident grouping is *stable* and *labile* on the basis of the study of

those functions most closely related to the behavior under consideration.

While the functional study based on psychopathology, noted when the animal is placed under rigidly controlled environmental strain, does not overcome all the objections of classification and is more time-consuming than the short-cut of making one or two physical measurements, it has enabled us to predict the breakdown of the animals more accurately than can be done by other systems.

Even in the first month of experimentation with Nick, a clue could be seen in his susceptibility to stress. Thus as referred to in his history, it was noted that he over-reacted to punishment on the very first day, by refusing to eat the next day, and again two weeks later he became extremely restless and refused food when the systematic elaboration of the first cr was started. In contrast no such behavior occurred in the two dogs, Peter and Fritz, subjected to the same routine.

Several important questions deserve consideration in a final evaluation of the results, in spite of their clearcut character.

First, are we recording chiefly individual patterns of reactivity in certain types or actual susceptibility to the imposed strain?

Second, are we measuring only susceptibility of certain physiological systems in the given individuals or of the whole personality? For example it is known that one person will break down with a gastric ulcer, another with arteriosclerosis, another with hysterical paralysis under stress and conflict. Third, is the conflict (situation of stress) that we introduce concerned with items that might be significant for the human subject or are they too trivial to be correlated with the important life experiences?

A satisfactory answer cannot be given to all these objections until further work has been completed. It is undoubtedly true that our tests do concern susceptibility of certain systems dependent upon the type of individual, giving us evidence not only of the susceptibility to breakdown but the functional type of the individual and the relative susceptibility of the various systems. The question of system susceptibility vs. susceptibility of the whole personality requires careful analysis; it should be met by taking several measures that show a high correlation with the personality rather than by using a single measure (*48*).

The predominating importance of the individual is evident in the behavior of Fritz, Peter, and Nick when the stress was increased. In spite of the terrifying experience of the explosions in the camera close to the dogs tied on the stand, the behavior was not markedly altered nor worsened beyond the point it had reached by the previous difficult differentiation. This is of extreme importance because it indicates that the *labile* may break down permanently and maximally under a light load, while the *stable* may show only a temporary disturbance regardless of the severity of environment. There are animals intermediate between these extremes.

Of more importance than the classification into groups, even with the use of

...ly correlated characteristics, is the thorough study of the individual. ... number of possible combinations of factors of susceptibility make the ... individual more revealing than is the statistical summary based on ... of a given characteristic in many individuals correlated with an average ... of stress in many different individuals. # IX. PSYCHOPATHOLOGICAL MECHANISMS

## Physiological, Psychoanalytic, and Sociological Explanations

The material of this monograph has been obtained by the intensive, prolonged and comparative study of a few individuals rather than by subjecting large numbers of animals to a set procedure. By this method we are able to see individual differences. And though we are unable to state what per cent of animals break down or what happens in the total population, we get a clear picture of what may happen to individuals.

A large number of animals is desirable when we want to rule out individual variations. But in a study such as this the individual is one of the important factors, and an average with other animals in a large group would tend to obscure just the thing we wish to observe. It is the detailed and controlled study of each dog separately and not the statistical average that reveals the mechanism of the disturbance; a statistical summary and average in such studies would tend to eliminate just those personality differences that we wish to see, leaving perhaps a zero result. If a given animal manifests the same symptom with clock-like regularity when brought into a certain environment over a period of years, we have facts that are as fundamental and unalterable as, and more significant than, those in a statistical survey covering hundreds of dissimilar individuals.

In defense of the method of intensive study of a few individuals, may be mentioned the importance of such careful continuous observations in an individual as were made by Beaumont on the gastric secretion in Alexis St. Martin, which provided the basis for much of the future work of the physiology of digestion. And most of the observations in this material, albeit from only a few individuals, could be again and again demonstrated (throughout a decade in the life of one dog) when the conditions were reproduced, thus giving ample evidence that they were not chance reactions.

An intensive and comparative study of individuals though made by different observers may enable us to accumulate data leading to a rational classification of types.

Because it has been possible to see in one dog (Nick) the origin and whole development of the various patterns, beginning in the acute stage and passing into chronic, life-long, stereotyped patterns, the discussion below is drawn chiefly from the studies of him. In almost any dog, however, one may see an acute disturbance the extent and duration of which depends upon both the procedure and the susceptibility of the animal.

As described in the historical review of Pavlov's approach to the experimental

...the "collision" of excitation and inhibition is sufficient to produce at least ...y disturbance. The variety of procedures which may be employed to ... such a disturbance have been described in Chapter IV. It behooves us ...tain what are the factors involved and what is the underlying mecha... disturbance.

...the acute disturbances we have to consider those which appeared years ...me chronic, and involved many other physiological systems than the ...ter of excitation (e.g., food or pain).

...concept of the collision of excitatory and inhibitory processes is an ...one with little direct factual evidence.[1] However it finds some support ...veries recently of excitatory (acetylcholin) and inhibitory (sympathin) ...by Loewi, Babkin, Wolff, Cannon, Rosenblueth, Rioch et al. An ex... such as this depends upon the actual existence of two simple independent ...s excitation and inhibition postulated by Pavlov.

...procedure may seem to be shirking my own responsibility and not living ...duty that I as well as other scientists recognize, viz., the courage to come ...lusions about one's own experiments (*36*, *89*, p. 30). However throughout ...graph I have given my own explanations of the events and the experi... at the time they were described. For me now to add to my explanation of the ...nisms a complete system of psychopathology would give the false impression ...I am ready to build up a whole new system in a field of immense complexities

[1] ...a state of affairs, however, is common in the physical sciences. For example, the structure of all ...of atoms and molecules, the electronic theory, the wave theory of light are fully as theoretical as ...Pavlov's theories of brain dynamics.

in which only an experimental beginning has been made. On the other hand more knowledge may be gained by an attempt to bring these facts in line with existing modern concepts of psychopathology as stated by several disciplined observers.

*A. The Pavlovian School of thought is represented by Ischlondsky's explanation by the principles of induction and irradiation.* Ischlondsky, the author of one of the best summaries of the whole conditioned reflex literature (*58*) has supplied an explanation of the involvement of other physiological systems in Nick based upon irradiation and induction.[2] In brief, Ischlondsky postulates that the excitation in the affective center, sets up on the principle of induction the opposite process (inhibition) in the food center but by irradiation the excitation spreads to the other centers. The law of induction is operative in the former instance and irradiation in the latter because of the greater intensity of the first excitation.

Thus the urinary and sexual centers become charged with excitation, and the conditional excitations make a functional path to these centers. Pain biologically is closely related to sexual excitation. Examples in nature of the gross functional relationship of pain and sex can be seen in the association of painful stimuli (e.g., the biting, ferociousness, and parallel vocal expressions) of animals during sexual excitation or coitus. Even the word "passion" has not only the meaning of intense suffering but also of sexual feeling. Masochism and sadism may arise on the basis of this close biological association of the emotions of pain and sexual excitation.

Ischlondsky says of the mechanism in Nick compared to the human being:

> A child is submitted to corporal punishment. The mechanical irritation provokes an excitation of the pain center. Under normal conditions the reflex reaction is a negative, defensive one. Likewise would a normal conditioned response be a defensive one, that is the aspect of the instrument of punishment, for instance, would provoke the same negative reaction of the child.
>
> Under favorable conditions, for example if the constitution of the child is particularly susceptible to irradiation of the excitatory process or if the environment is especially conducive (humiliating circumstances under which the punishment is afflicted, presence of other children, etc.), the excitation of the pain center, having reached a certain intensity, may spread over the neighboring brain portions and reach the sexual center, releasing from there a sexual reaction; owing to the intermediary of irradiation, we obtain an inappropriate positive reaction, and since the conditioned stimuli of the environment coincide in time, such circumstances develop an inappropriate conditioned reflex so that the mere aspect of the instrument of punishment will lead henceforth to the same inappropriate reaction. It is evident that my scheme of indirect conditional-reflex connection has one link more than the Pavlovian scheme of direct signalization, the additional link being supplied by the irradiation from the pain centre to the sexual centre.
>
> The same is valid for the process of induction, with the only difference that an excitation

[2] For an explanation of these terms see: Pavlov (*88, 89*).

... centre (B) would lead to an inhibition of the secondary centre (B') and ... an inhibitory reflex, and vice versa.

B. 7. ... *interpretation according to psychoanalytical principles.* Alexander, Saul, ..., Murray have pointed out the probability of the personal relationships ... in the production of the experimental neurosis in Nick. It was from these

early suggestions that my experiments on the human factor in Nick's behavior were investigated. As has been described, reciprocal relations were definitely found to be operative, thus the symptoms of anxiety were ameliorated by the presence of a human being, and conversely Nick developed a negativistic attitude with marked respiratory and cardiac changes toward these persons.

French considers Pavlov's positive cr as equivalent to "an affective association", conditioned inhibition as parallel to Freudian repression. External inhibition is equivalent to the repression based upon an extraneous motive (fear), and internal inhibition, equivalent to failure of gratification.

Dr. Leon Saul[3] has very kindly furnished me with the following explanation of Nick's symptoms, in so far as they may be compared with these human relations.

From the clinical psychoanalytic standpoint the behavior of Nick suggests the following interpretation:

There are at least two factors in operation in his neurotic behavior. One is the actual experimental procedure which provides two stimuli to an important reflex function in such a way that the dog is unable to discriminate between the stimuli. This produces a state of indecision. This is also analogous to conflict in human beings. For example, one girl was in a state of aggressive neurotic confusion. Her parents were divorced. When she lived with her mother, the latter exacted extreme puritanism, and then during the other half year she lived with her father who was not only very free in alcoholism, promiscuity, etc., but encouraged the girl to be the same. A much more common clinical variety of this conflict is seen in the second generation son, conditioned by his father to ideals of success, independence, self-made man, etc., but by his mother to being soft, dependent, indulged, spoiled by her. It has always seemed to me that this type of conflict is quite analogous to that seen in animals conditioned to salivate to one stimulus and not to salivate to a closely similar one. However, the level at which this conflict takes place is not clear. It is probably at a rather low level, far from consciousness although higher levels could be secondarily involved. The second factor is the dog's reaction to the entire experimental situation as opposed to the detailed procedure of the experiments. The relations to human beings are one part of the entire experimental situation. That is, the dog is placed in a situation which is very disturbing. He therefore develops a dislike of this situation and a resentment against it. It is common knowledge that dogs have a very high capacity for attachment to their masters and this factor must be taken into account in order to be able to understand a dog's behavior. In this case, it seems clear that the dog becomes defensive and resentful not simply toward the uncomfortable laboratory situation but also against his master who is the experimenter who treats him this way. In other words, the dog becomes conditioned against the entire disagreeable situation. If this treatment of the dog is continued the dog becomes resentful not only against the experimental situation and against his master but against the entire laboratory and perhaps against all the surroundings, and everyone and everything associated with them. In other words, resentment spreads in the well known clinical fashion of the spread of a phobia. (In human cases an individual may

[3] Comments by letter.

a certain street and then this fear spreads to include the entire street and then ...t, perhaps even the entire city and so on.)[4] Perhaps his hostility may spread ...men, or all human beings. The evidence of the dog's hostility seems quite clear. ...ed toward Dr. Gantt, he emits a foul odor, endeavors to run away from ... toward other people. The neurotic, that is abnormal, behavior of the dog can ... as follows:

But, opposed to this attachment is a ...ncy to Dr. Gantt's treatment of him in the experimental situation and also a ... from Dr. Gantt, and away from the entire threatening and traumatic situation. ... Gantt takes him to the laboratory these opposing tendencies come into sharp ... the one hand is the tendency to be obedient and well behaved with his master. ... hand he fears and hates the experimental situation and tends to rebel against ...llowing Dr. Gantt, probably feels very hostile toward him and wants to escape. ... were an undomesticated wild animal he would probably indulge these latter im-...acking Dr. Gantt and trying to flee. But because he is domesticated, that is, tends ... docile and obedient and because he has a positive attachment for Dr. Gantt, he ...ge his primitive defensive impulses of fight and flight. These impulses are acutely ...wever and can be thought of as an intense excitation of instinctual origin. Because ...st remain well behaved this excitation cannot be adequately discharged in direct ...ve action. It is pent up and seeks discharge in other directions. This is apparent in ...l excitement of the animal consisting of restless movements, urination, erection ...gns of vegetative and somatic activity. All of these activities can be interpreted ... outlets for the excitation which cannot be discharged along primitive patterns of ...fight. That sexuality can drain excitement of all kinds is a well-known clinical ... in humans. Many individuals who find themselves in frustrating situations obtain ...masturbating and also by sexual relations. Urination is also exactly analogous to ...e observed in human beings. Many persons, perhaps women more than men, when ...me excited become slightly incontinent of urine, sometimes violent laughter is enough ...n this. Even closer to the experimental situation of the dog is the analytic situation. ...ery common observation that patients who have considerable anxiety about their ...nd who force themselves to come in spite of feelings and wishes to stay away or ... marked frequency of urination. They say frankly that they do not want to come ...our, feel nervous and urinate several times before the hour, immediately afterwards ...times must even leave the hour to relieve themselves. This situation is almost identical ...t of the dog, coming against his will to the experimental situation. I am sure that ...psychosomatic and behavior symptoms manifested by the dog could be closely paralleled ...l observations.

...general behavior of the dog toward the experimental situation and toward Dr. Gantt ... characterized as a type of anxiety with phobias, certainly the latter. He wishes to

[4] ... example see—Fenichel—Outline of Clinical Psychoanalysis, New York, Norton, 1934: pp. ...

shun everything associated with this disagreeable experience. A connection with the [illegible] neuroses is apparent.

As to actual content of some of the dog's behavior, one point is very suggestive. The dog is seen to run up and down the steps, back and forth. Such behavior finds a certain analogy in the clinical condition of compulsion neuroses which is characterized by opposing tendencies which may either create doubt or else may be acted out in succession, first one way and then the opposite. (Freud, The Rat-man [20], the patient of Freud who removed a stone from the road and then put it back.) Although these remarks are less certain than the above, it is at least suggestive to relate this behavior of the dog to the content of the [illegible]. That is, the dog's uncertainty in behavior, repeatedly reversing himself, may be a manifestation of a condition produced by the experimental situation which was also one of [illegible] the dog being placed in a situation in which behavior in one direction or another [illegible] definitely affected by the stimuli.

These reactions of Nick are most fascinating from the analytic point of view. The drop in heart rate (in the country) is of course exactly what one sees with human beings when they are removed from a situation which stimulates their anxieties or hostilities. In analyses, during periods in which the patients' resentments are mobilized, one very often finds increases in heart rate, as well as frequently extrasystoles. As to Nick's reaction to the food, that is a typical example of "soiling aggressions." The use of urine and feces aggressively was pointed out by Freud and is seen in varying degrees in the dreams and fantasies of almost every analytic case. Relationships with bowel disturbances such as functional colitis and constipation have been dealt with by various authors, most completely by Alexander and his associates in the Gastro-Intestinal Symposium of this Institute. Dr. Margaret Gerard has touched upon the aggressive significance of urination in her review of enuresis. Certain patients when they become angry dream of soiling with urine or feces. Indeed a careful search through the dreams of our gastro-intestinal cases would probably reveal a few very similar to Nick's actual behavior. This aggressive use of the excreta is clearly reflected in popular [illegible] and is seen in the practices which have been reported from Germany and also during the last war in which troops would defecate on the floor of occupied houses and would hold [illegible] in the latrines and sometimes directly urinate and defecate on them. The connection between anal activity and sadism was first pointed out by Freud and the study of these relationships has been the main work of Ernest Jones. There is considerable evidence that all children go through a stage in which anal and sadistic impulses are important in their psychological organization. The erection fits into the picture perfectly.

I would reconstruct the situation about as follows: The appearance of the food, through its associations with the painful and traumatic situation of the experiment, arouses in Nick a reaction of rage. This rage is in the nature of a defense reaction against having anything to do with the painful situation. The physiological tension of the rage is relieved through the soiling which has a hostile, aggressive meaning, and the same excitement also produces the erection. It is a well established clinical fact that any emotion that is strong enough causes some sexual sensations, or manifestations, as though the sexuality were one method of relieving physiological tensions. A business man, frustrated or excited in some deal, may go out with a prostitute or masturbate. With the sexuality there is probably a direct physiological

[illegible] "I just heard that if food is taken away from a monkey, he may react with [illegible] going off and masturbating." This relationship has been expressed [illegible] saying that the emotion gets "eroticized" or "sexualized." I have a patient who [illegible] when he gambles, and finds this more exciting than actual sexual relations. This leads to the very interesting question as to whether the expression [illegible] urination and defecation is a natural biological reaction in the dog or whether [illegible] of his training in cleanliness, that is, of the cultural factors. It is generally con[illegible] children do not use the excreta obscenely or aggressively until after they have [illegible] to cleanliness and learn to consider them dirty and disgusting and thereby dis[illegible] can use them as a means of defiance, depreciation, etc. If Nick had never [illegible], he might not have used the excreta in this way. On the other hand it [illegible] through his ambivalence, his affection for Dr. Gantt was strong enough to inhibit [illegible] manifestation of aggressiveness, such as direct attack, and therefore the hostility [illegible] through the visceral activities of urination and defecation and also sexuality [illegible] of the current theories of the psychogenesis of organ neuroses, as discharge [illegible] nomic nervous system of nervous excitement not discharged through the normal [illegible] activity). A third possibility is that the eliminative function, particularly the [illegible] involved because the stimulus was food. This would mean that the behavior [illegible] as well as an aggressive meaning. This receives some support from the [illegible] Nick took the cracker into his mouth and then dropped it and then eliminated on it. [illegible] is seen in hysterical nausea and vomiting on a similar basis and the eliminat[illegible] in diarrhea is clearly discussed in the Gastro-Intestinal Symposium. His heart [illegible] be some index as to the importance of the role of the hostility which I should [illegible] main reaction, particularly since the urination and erection were also observed. [illegible] then, I would see it about as follows: He is offered the food; this reminds him [illegible] situation (i.e., not only of the personal relationship which operates more as a [illegible] repression), he therefore spits it out. Possibly his impulses to eliminate are so [illegible] by this that he also defecates and urinates. However, the defecation and [illegible] are clearly not results simply of diffuse excitement, since they are directed at the [illegible] offending reminder. Using clinical experience, this would mean that rage was [illegible] the food and this was expressed against it by excreting. Moreover, the emotion [illegible] enough also to stimulate sexual excitement. So far as the eliminative impulse is [illegible], this might be a primitive one, independent of any training, but the soiling of the [illegible] suggests that the training in cleanliness plays a role in the choice of just this form of [illegible], just as babies who are ordinarily well trained will sometimes soil themselves if [illegible] made angry.

Dr. Saul as a representative of the psychoanalysts has emphasized in the above [illegible] the powerful influence of the social factors. These have been frequently [illegible] to in the history of Nick: with him, as I have demonstrated, the same [illegible] being has both a temporary inhibiting effect on the anxiety and paradoxi-

[illegible] by Ischlondsky as the law of induction and irradiation.

[illegible] Klüver's and Jacobsen's experiments referred to previously in this monograph.

cally the ability of eliciting the disturbed behavior; moreover the prolonged friendly association of the experimenter with Nick on the farm "cured" him in that particular environment. There are other striking analogies between the above clinical symptoms and those of the neurotic dogs and many of the explanations which Saul offers seem to fit the material of Nick.

But the fact that the disturbances occur in an isolated experimental environment and at first apparently independent of the experimenter, in spite of any connection that he may later acquire, as well as the fact that such neurotic behavior is seen in a variety of animals as shown by Liddell working with the goat, pig, sheep, Finch and Jacobsen with the apes, Bard and Rioch, Masserman, Karn and Dworkin with cats, Maier, Cook and others with rats indicates that the disturbance of behavior can occur in animals in whom there is no reason to believe that a personal relationship to the human plays a role. Furthermore the fact that in the dogs it is not only related to the total environment but also more specifically and pointedly to the induced conditioned stimuli indicates that besides the personal relationship which evidently is a factor in our dogs, there may be at the same time a more mechanistic basic physiological principle involved as outlined by Ischlondsky.

Here we may recall that Pavlov (*88*) noted and experimented with the social factor in dogs made neurotic by the Leningrad flood, but he did not show the ramifications brought out with Nick, nor did he place as much emphasis upon it as the psychoanalysts do.

Although Saul[7] recognizes that "biological reactions, e.g., rage, are important whether generated by personal or impersonal situations," frequently the over-emphasis of the Freudian explanations by others leaves one with the impression that the personal relationship is everything—a view as unsubstantiated as the strictly mechanistic one of the reflexologist.

The explanations of Ischlondsky and of Saul provide striking analyses of the mechanism of the sexual manifestations in Nick. It is possible that each may represent a different aspect of the same mechanism; e.g., the quality of heat may be expressed by the physicist as a motion of molecules, by the engineer as the ability to move a piston and by the physiologist as an effect upon sensory nerve endings. A cow is a collection of chemical compounds, an animal that gives milk, and an object having a certain financial value. None of these aspects are exclusive and each is useful in a different way. Clearly our point of view must be determined by pragmatic considerations, viz., the significance of the concept for the field in which we are working. If this field is therapy the use of those principles of proven therapeutic value is required; but research must make room for revision of concepts leading to new methods.

[7] "Basic conceptions of psychoanalysis are grounded on the understanding of biological development and functioning, an important part of which, but only part is the emotional relationships with other persons." (Leon Saul, personal communication.)

...ther or not the above explanations would suffice for a general expla... nervous disturbances is a question subject to the following considerations. ...read connections of the sexual function, its intensity and predominant ...e facts which cannot be doubted. But in most dogs, as well as patients, ...ptoms are not nearly so marked as in Nick or may perhaps be absent. ...patients of Whitehorn, Rosen and Barker, mentioned in Chapter VI ...al instances rather than ordinary ones. I do not deny, however, the ...a much more widespread latent sexual excitation which may exert an ...without a direct expression in the sexual system. Some psychiatrists, e.g., ...ann (1?3), in contrast to the psychoanalysts even fail to find any sig... in the sexual erections of young children, while others would trace this ...p back to an antenatal condition (Greenacre [51]).

...Nick's symptoms are so similar clinically to anxiety, it is interesting to ...e how closely the origin of his symptoms fits in with the Freudian ex... ...of anxiety. These have been clearly stated by Greenacre. The origin can ...tly traced back to a known and artificially produced conflict, but it is ...to see how the birth trauma in Nick could be a prototype. It would seem ...ssible that such marked sexual phenomena in nervous disturbances occur ...ly in a certain type having a susceptibility of the sexual function, just as ...cer is seen in a nervous type with a special susceptibility of the gastro... ...l system. According to this view any autonomic function might be in... depending upon the individual susceptibility, and though the sexual func... ...ld, on account of its intensity and predominance often be the basis of ...the symptoms it would not necessarily be the origin of the conflict. Thus ...al system might be on a par with other autonomic functions—a collateral ...than the original center of the disturbance. Naturally the sexual as well as ...ymptoms would, in proportion to their intensity, be widely connected with ...functions and subjective feelings. This concept is in keeping with the views ...are loosely expressed by the current term "psychosomatic." While such a ...t gives to the sexual function a predominating influence according to its ...intensity, it does not make the sexual function the necessary center of ori... ...as leaving room for other disturbances to develop, to use a physical analogy, ...allel circuit rather than in series* with the sexual excitation.

...*The socio-anthropological explanation.* Another concept of the contrasting ...in man and animals is that of Alexander Leighton, a pupil of Adolf ...er's, and a serious student of anthropology. Leighton's summary is derived ...a broad sociological point of view.

...the common ground for man and animals:

...tendency to stay alive is characteristic of all forms of life and in most creatures is a ...nant urge that underlies much of their relationship to their environment. It may take

two general forms: (1) predatoriness, in which objects are overcome and made to serve the animal's needs or, if potentially dangerous, destroyed; (2) avoidance, in which objects are ignored or, if potentially dangerous, fled from. For many animals the world is a place composed of positive and negative objects, which he examines and deals with by either predatory or avoiding methods. The issues are essentially clearcut. As an animal you exploit the world for food and shelter and you stay alive by overcoming those organisms you can and by running away from those that you cannot, and it is not usually difficult to tell which is which.

Co-dependence Leighton emphasizes is a main difference between man and animals:

Man differs from most other animals in being utterly dependent on his fellows for his basic biological needs. He cannot stay alive apart from his own kind. This does not mean that individual human beings have never succeeded in living alone, but it does mean that the human race, in the numbers it has today, in a world with the size and resources of this one, could not survive two months without close cooperation. Man is as dependent as any horse or cow, and would fare just as badly if turned loose alone in the jungle. Where other animals maintain life in an environment made up of all sorts of things, man finds that the most important part of his environment is essentially one element, namely his own kind.

Out of this social dependence comes both our strength and weakness, and as Maeterlinck (77) says, in the long run it may be our undoing:

Our adversaries have always been isolated, unconscious; and for these thousands of years the one enemy that really counted has been ourselves.

Leighton continues:

The urge to live is as strong in man as in any other animal but, due to this social dependence, it is dynamically more directed at social factors than at clearcut issues of obtaining food* and avoiding attack. Therefore people are more shaken by disruption of personal ties than by financial disaster. It is not to be inferred from this that a person must think each time he shakes hands or buys a suit of clothes that is in fashion or carries out some other social act, "I am doing this to preserve myself," any more than he has such thoughts each time he eats a sandwich or stands on the curb until the traffic goes by. Nevertheless, social relations and activities have these biological significances related to security and survival. In terms of natural selection, one may say that people who were unable to develop traits that make for social adjustment died early or were killed off by their fellows.

As I have pointed out, the dog has adopted many human qualities. Many instances have been given in this monograph of the social relationships between the neurotic dog and his master, comparable to interhuman relationships.

* This is clearly brought out in cr experiments using the food reflex in human adults—the food reflex is so subordinated and easily inhibited that it is difficult to evoke by the ordinary means used with animals. (W.H.G.)

[illegible] social environment be treated with the simple predatory and avoidance [illegible] by the lower animals? To some extent it can. One can preserve his sense of [illegible] being predatory, by being so powerful and terrible that all others are afraid of [illegible] preserve his sense of security by submission and the avoidance of conflict. [illegible] the individual and his social environment there is a third possibility, re[illegible] represents a matured form of the relationship that exists between a [illegible] parents. "If I love and obey you, you will love and protect me." Between adults "If I help you, you will help me." The Christian Golden Rule is a high ethical [illegible] this.

[illegible] the conflict in the human being is described as involving different ends from [illegible] laboratory as the basis for the experimental neurosis in the dog. Our experi[illegible] that social factors have an influence also in the dog but to what extent and [illegible] so cannot be determined. The psychoanalyst would place much more [illegible] relationship than has hitherto been done by those working with experimental [illegible] much of a factor this is in the animal is a question for future research.

[illegible] submission and reciprocity are the three principal methods of achiev[illegible] and survival in a social environment, there will be some people who will [illegible] method most of the time, while the majority of people will practice all three [illegible] of the time. The natural outcome of this is confusion and uneasiness on the [illegible] individual. In his social environent he is utterly dependent on his fellow man, but [illegible] time he doesn't know how or where to place his dependence. He knows that a [illegible] predatory, and he knows perhaps that his children will submit to him and he knows [illegible] friends are square with him, but by and large he knows that people are likely [illegible] and can very well seem to be one thing while they actually are another. [illegible] associates reciprocal or are they trying to steal his customers? Are his cus[illegible] to pay him? Who is predatory, who can be trusted? What of the neighbors? [illegible] politicians, through whom the welfare of the nation is sought? What of the [illegible] that is supposed to protect? Are all these reciprocating with him when he pays [illegible] are they treating him in a predatory fashion and using what they can get out of [illegible] own ends? Are his friends likely to take advantage of his leisure moods to put [illegible] him to niches of social position? He can be sure that there is great striving, [illegible] expect from whom and when is often unclear. Life is a game that requires him [illegible] moves against opponents and with friends, many of whom are not playing [illegible] to the same rules.

[illegible] I have spoken of a man as if he were the victim of social Brownian movement, but [illegible] and blurring of outlines is no less when he is considered as a more active [illegible] If he is reciprocal at the wrong times he will be swindled. If he is predatory at the [illegible] will reap the prestige of power and position, but if he does it at the wrong time [illegible] a social outcast. Worse than this puzzlement, he may actually hold several [illegible] roles in the structure of his society that put conflicting demands upon him. As a [illegible] predatory activity may be forced on him as a necessity in order to gain sub[illegible] social life it may be required of him that he be strictly fair and reciprocal; at [illegible] order to hold together his other securities, he may have to be submissive. In actual

being these things cannot be kept separate. What is he to do when a friend wants to borrow for his business purposes at a time when his own family needs money and the only way to get it is to treat the friend with predatory methods? In close and intimate human relationships, this uncertainty is no less. The most trustworthy partner in a reciprocal relationship in one set of circumstances may at the very same time be predatory in another set.

I have, up to this point, considered social relations only from the biological foundation of survival. If now, we consider them from the equally biological foundation of sexual trends, it will be at once apparent that the opportunities for confusion are vastly increased. Even when the individual knows perfectly well what he should do for his own best social survival, he is often tempted into relationships which snarl up all his other dependencies.

In short, man is exposed to the greatest complexities at the points where his urge to live is most dependent—his social relationships. Culture is the establishment of patterns of behavior that are commonly shared and which therefore bring some clarity to the issues. In well established societies most of the hopeless confusion which I have described above may not exist at all. However, in periods of rapid change and in the mixing of many cultures together, confusion tends to predominate over the patterns, and the patterns which do exist are often fairly contradictory. For example, a large number of Americans believe simultaneously that (1) Every one should try to be successful, (2) The kind of person you are is more important than how successful you are; (1) Honesty is the best policy, (2) Business is business, and a business man would be a fool if he did not cover his hand; (1) America is a land of unlimited opportunity and people get pretty much what is coming to them here in this country, (2) Of course, not everybody can be boss and factories cannot give jobs if there are no jobs to give; (1) Education is a fine thing, (2) It is the practical men who get things done; (1) Paternalism and public service are fine things, (2) Of course a man has to look out for himself.

Leighton thinks that the pattern of the conflict in man is probably related to that of the experimental neurosis:

The experimental "neurosis" in animals shows that when an animal is confronted with two conditioned stimuli that it has great difficulty distinguishing, the animal tends to break down. It seems reasonable to suppose that human beings are "conditioned" to various social stimuli and, as a consequence of the confusion and blurring in the social environment just described, have the constant strain of making difficult discriminations. Human neuroses may in part be reactions to such situations, and thus have a relationship to the experimental "neuroses" in dogs. The idea might be formulated thus: Any given break is the product of the constitutional tendency to that reaction and experience with chronic difficulty in discriminating points of social orientation that call for different action.

The parallel between a functional constitution in the dog and in man is evident.

It is possible that some people will object to considering the urge to live as fundamental in the dynamics of human behavior, since it is often seen that men hold life to be cheap in the face of other values. What of the soldier who gets himself shot in the performance of duty?[3] In most instances such actions can be seen clearly as the result of the person valuing the esteem of his fellows and therefore his security in society above the risk to life. He takes

[illegible] and hopes to come out of it with profit, like Steve Brody, who jumped off the [illegible] Bridge and gained fame and fortune. The need for security in society has come to [illegible] the most primitive urge for immediate safety. However, there are instances in [illegible] this sort of perception will not work. The martyr, who will allow himself to be [illegible] at the stake rather than recant is an example. He goes to certain death and knows it.

There is undoubtedly a basis in the life of all animals for anxiety, viz., the real [illegible] of insecurity. Nearly all animals including man in his wars are hunted [illegible] by others. Then there is the insecurity based upon nutrition, etc., it [illegible] in the last century that the human being has found it within his means to [illegible] himself of this latter form of insecurity.

The mechanism of conditioning to distant stimuli and of what Pavlov would [illegible] conditional reflexes is brought in at this point to show how this [illegible] conditioning may drive the human being to his death.

[illegible] the concept of conditioning will help explain this. At some time in his life the [illegible] invested his total sense of security in a set of beliefs and values. The unconditioned [illegible] was the need for affective satisfaction relative to security. The conditioned stimuli [illegible] of the creed and the ritual. There was no extinction in the course of the [illegible] of these conditioned stimuli, because the affective needs were always [illegible] the martyr. Therefore when he is at last faced with the necessity of giving up his [illegible] of making the final gesture of investing all in it, he dies at the end of [illegible] of religious conditioning with his eyes on security beyond the grave.

[illegible] extreme form this sort of thing is seen every day. People form attitudes and [illegible] of growth and development, and later run into situations in which they are [illegible]. Rather than give up the attitudes in which they have invested their sense of [illegible] and which give them emotional satisfaction they will run counter to all the require[illegible] adjustment to the immediate social circumstances.

Rosenzweig and others have stressed the widespread character of what is gen[illegible] considered under the term of frustration (60). Jacobsen's production of [illegible] and whimpering in chimps after making errors in distinguishing [illegible] cup food was placed can be referred either to frustration or differen[illegible] too difficult (59).

This would seem to involve the principle of excitation without gratification. As [illegible] described in Chapter IV, when the US follows in proper sequence the [illegible] excitation, all the cr activity is arrested and there is a refractory period [illegible] which the animal is not subject to stimulation by any other stimuli having [illegible] the same basic excitation. However if the US for any reason whatever [illegible] in its proper place, or if there is too long a delay between the cs [illegible] the US, the animal becomes restless and the cr activity is prolonged and ac[illegible] by a generalized spreading of the excitation to involve extensive mus[illegible] activity and chaotic relations in the autonomic system such as increased and [illegible] respiration and cardiac rates.

Such a state of affairs may eventually lead to a non-specific spreading of the excitation or it may develop into a chronic inhibition which may remain localized or become widespread. There is much evidence accumulated in this laboratory that inhibition is an active process, really a negative excitation ([illegible]). Both the respiratory and cardiac rates attest that inhibition is an active process ([illegible]). This has also been shown in Pavlov's laboratory by the phenomenon of disinhibition, where the inhibitory process becomes excitatory, transferred into the specific excitation upon which it was based.

If inhibition is considered then as an active though blocked excitation in the nervous system not extending to the efferent and executor organs involved in the original positive excitation, such as the grasping and eating of food—it is either still present as a potential excitation, or on the other hand it may remain blocked as regards its own specific excitation but overflowing into new physiological systems. Such an extension may be considered to occur on the basis of Pavlov's principle of induction, or more simply as a local damming with generalized overflow of the excitation.

Induction would explain the general excitation as a direct result of the specific inhibition in the center concerned (food, defense), but induction as met with in the experiments is a transient phenomenon lasting only a few minutes or seconds, and therefore the concept must be extended and so modified that it applies to the more complex and chronic manifestations as well as to the artificial crs. Although the two processes of induction and irradiation do give us a hint of the laws governing a simple type of spread of excitation and inhibition, substantiation of the same mechanism in such complex chronic phenomena has not been carried far enough in the laboratory to be of more than theoretical interest here. It must be considered as a descriptive term for a phenomenon clearly demonstrated for simple crs but only an hypothesis for prolonged effects, and even then not entirely explanatory. It deserves ranking with other hypotheses for verification. Even though induction operates similarly to the way it does in the laboratory, the law of induction itself explains little, as we do not know when or why it operates, in spite of Pavlov's having demonstrated its frequent occurrence. The question of why induction seems to be active in Nick (e.g., inhibition of food center in Nick causes excitation of the sexual center) and not in Fritz goes back to the much more important fact of "constitution" referred to in the previous chapter. Until more light is thrown on these individual variations we are still in the dark.

Guthrie's theory of a failure to extinguish pathological reactions because the subject avoids the csi which might lead to extinction cannot hold in the animal experimentation because Nick and the other dogs were constantly subjected to the procedure which would produce extinction of the crs.

From the comparative study of a wide range of animals, from the rat to the

... and man one may conclude that the production of a disturbance of ... not peculiar to the human being. Many of the objective symptoms in ... animals have a close resemblance—to mention a few, the palpitations, ... and motility disturbances. Not only in the dog and rat as shown ..., Löwenbach and Gantt (7?), Maier (79), does one see cataleptic ..., but even in such lower animals as the spread head moccasin. This inhabitant of the Eastern U.S.A., attempts to discourage attack by ferocious ..., wide opening of the mouth, and expansion of the neck through in... Failing in this, the serpent turns upon its back, becomes rigid and ... It remains motionless unless its relation to gravity is changed by ... animal, or lifting it by the tail, when it again flips over. Such a state is maintained in the face of a danger which threatens or destroys ... seen such snakes continue in this cataleptic state even though they are ... contact with the heat of fire, allowing themselves to be burned; or ... with the predicament of being devoured by a hog, preserving their ... while the hog is in the process of picking them up and chewing them.

... notorious example is the opossum who will permit himself to be bitten ... by dogs—the enemies he is avoiding—before coming out of the immo... he has assumed for protection.

... vertebrates may pass into cataleptic states, e.g., frogs, crayfish, the spider ... stick-insect. That such a state is due to the higher parts of the brain can ... strated in the stick-insect by removing the head ganglion, after which ... does not appear (*106*). The resemblance of this condition through... animal range to catalepsy in catatonic patients is striking.

... remarkable instances are mentioned here as evidence of the widespread ... of psychopathologic processes in all animals in spite of individual and ... variations.

... has described cataleptic conditions in dogs as a result of conflicts of ex... and inhibition in which the animal becomes as rigid as a statue, particularly ... muscles which were involved in the former excitation, the muscles of ... and of the jaws and neck and to a lesser extent the forelegs and trunk ... at all of the hindleg. The motor system is chiefly involved and the ... conditional reflexes may remain unaffected—the dog may drool at the ... at the sight of food but remain rigid in front of it.

... withstanding the fact that a pathological disturbance of behavior is a com... attribute of a variety of neurotics, undoubtedly generic as well as individual ... exist, both as to the etiology, origin and symptomatology. One of the ... differences between man and other animals is based upon the development ... and symbolization. In this system arises the possibility of innumerable ... and elaborations. Thus in addition to the accumulation of conditional

signals during the life of the individual are the vastly more numerous word signals and their connections and interassociations. Pavlov has postulated that people fall into two general groups, artists (those with eidetic imagery) and thinkers, the former reacting to the direct conditional signals and the latter to the signals of the signals, viz., speech representations; the symptoms of hysteria result from a weakness of the second signalling system (*31*) (*80*).

### Conclusions

The new objective approach to the study of nervous imbalance cannot yet, owing to the fragmentary nature of the work as well as to the enormous complexity of the phenomena, give a complete explanation to the problems of nervous breakdown. But certain definite principles emerge, as pointed out throughout the monograph, which apply to a variety of animals including man with certain modifications according to each species. Because of the objectivity of the method we have a basis for observation and experiment, the possibility of comparing the results of various workers, and the hope of greater progress than that which comes from pure speculation.

The foregoing instances of catalepsy and of psychopathology in general (like the phenomenon of peptic ulcer or of sea-sickness or the pain of renal colic) are examples of the lack of perfect adaptations, of the perversion of "meanings," and of the persistance of a mechanistic physiological principle which though it may have originated on the basis of configuration to structure and environment, has become detrimental rather than helpful to the individual. Granted that the hyperacidity of peptic ulcer or the state of arterial hypertension can be related to agression, one is still at a loss to explain, for example, as pointed out by Bard (*91*), the "meaning" of the pain in renal colic or the loss of equilibrium and nausea in sea-sickness. Certain it is that the pain has a meaning for the patient but it serves no useful purpose and it originates only on the basis of a badly integrated mechanism. It is less anthropomorphic and more in line with objectivity to consider that our isolated physiological mechanisms exist in structure and "constitution" (as ill defined as this term is) acting blindly; for we must admit that the laws of nature are blind to our logic and feelings. On the basis of known physiological function inherent in structure and evoked by environment (internal and external) the phenomena are comprehensible but on the basis of origin from an integrated "meaning" they are meaningless. Symptoms like hysterical paralysis may arise on the basis of symbolism, others originating from function inherent in structure and environment. Nevertheless the feeling that they give rise to after they have occurred is assimilated by the individual and used symbolically, and in this way they may assume an integrated meaning for him (*post hoc ergo propter hoc*).

Such a view does not deny the interaction of physiology and psychology, of course

... the potency of suggestion and symbolism, but these do not nece-... according to the pattern of our conscious and well reasoned "mean-... If the word is intended in a strictly biological sense a less confused, less ..., and less anthropomorphic one is desirable.

... has been a tendency to cling to "meanings" and symbolism too exclu-... sole explanations of behaviour—reminiscent of the place assigned to ... by our ancestors. Such fallacy was strikingly demonstrated by Fran-...i, Florentine astronomer, who justified himself in denying Gallileo's ... of Jupiter's moons by the statement:

...satellites are invisible to the naked eye, and therefore can have no influ-... the earth, and therefore would be useless, and therefore do not exist."

...organisms *tend* toward integration of their activities and of their adapta-... has been emphasized by a host of philosopher-scientists, from Aristotle ... Darwin, Smuts, Jennings. In this sense they differ from the automaton ...rtes. Furthermore this integration usually has some purpose, directed ... an end, for the organism. But there are also involved in the various func-... "blind" mechanics, which though ordinarily integrated for the purpose of ... organism, may under certain circumstances assume an independence not ...ized with the best purposes of the organism. The energies of the individual ... mis-directed—neither for efficiency nor pleasurable ends nor for preser-... of life nor for the offspring nor for ultimate good—but because of imper-...ptations the living unit or a part may react in such a way as to defeat all ...ls. The resulting chaos may end either in mass disorganization, such as ...ented by war, or in individual disorganization leading to the neuroses ...choses. Our aim should then be not to insist upon the inexorable function-... universal principle but to find out by observation and experimentation ...*hat conditions* the various principles work.

...additional concept to these two principles of organization and mechanics ... added to give a more complete picture: Apparent chaotic symptoms and ...ons such as those of the psychotic, being the result of a special attitude, ...serve a certain function for the organism, in relieving tensions. From this ... of view it might be unwise to try to remove symptoms without attention to ...basic attitude (Whitehorn, *91*).

...titude is as important a determinant of the response as is the stimulus; the ...n of an animal to the same stimulus may depend entirely upon whether he ...ngry or angry, and this in turn upon the setting. For example, a honey bee ... hive will aggressively attack you, but in the field she will take pains to avoid .... Touch a dog while playing and wagging his tail or again on the identical skin ... while he is fighting; the same stimulus will at one time make him lick your ...nd, at another time bite it. Or stand with an ear of corn in your hand before a

hungry bull seeking food and again with the same food before the same [illegible] enraged and pawing the ground!

The internal state of the animal is equally as important as the external [illegible] whether CS or US. This has been pointed out with the food or Chute salivary and cardiac components, fig. (7). Also Sears found that sexually starved roosters mounted hens whom they had formerly avoided "as if with loathing." D. M. Levy reported that nearly all adolescent children sent to him for stealing sugar were on a diet deprived of sugar, an observation in line with Richter's rats seeking what is deficient in their blood.

It is important to recognize that the laws of psychopathology are not always the same as the laws of normal behavior. The spontaneous development of the system "neuroses" in Nick and their persistence is evidence that the pathological conditions arise according to laws differing from the physiological, probably by some mechanism of internal conditioning similar to what I have described as "intraneural" conditioning (9, 73).

Intraneural conditioning is based upon the introduction of stimuli within the central nervous system instead of from the outside. Although such stimuli were introduced artificially it is reasonable to suppose that the spontaneous fluctuations of excitation and of thresholds in the nervous system based upon internal rhythms of secretion (95) and other unknown factors may act either as stimuli or determinants of attitude. Such factors (determining the state of the organism) complicate the picture and introduce an element of unpredictability. Whether or not spontaneity as described by Adolf Meyer, free will, etc., is identical with the fluctuating state of the organism cannot be solved by any laboratory experiments so far performed.

In contradistinction to the normal conditional reflexes, the pathological reactions persisted for years without apparent reinforcement. However a certain type of reinforcement may occur on the basis of internal-emotional states which in turn may be initiated or elaborated on the traces of past stimulations. The echo of the emotional states on the cortex, through various afferent stimulations, proprioceptive, etc., conceivably may act as reinforcement for the trace stimulations in the cortex ("memory") which the emotions aroused, as has been proposed by Ischlondsky. This being so, we have a closed system within the organism of automatic effectual reinforcement not subject to ordinary extinction. There is overwhelming evidence that the emotional states do persist, but whether they occur in the same relationship and on the same pattern (cs—cr—US—UR) is entirely hypothetical. But the work of Light and Gantt (73) and others show that the external aspect of the UR is not necessary in this chain for conditioning. The conclusion from these experiments of eliminating the effector organ and those of Loucks (74, 75), Gantt and Brogden (8, 9) in elimination of the afferent limb of the reflex arc

...at the conditioning procedure depends essentially upon the central struc-

...the light stimulus after only a few associations with the tone in the patho-...al (Nick) rapidly acquires the ability to produce the same state in the ...the tone does, although the light itself was at first neutral and had had ...ship to the original conflict, indicates that the pathological condition ...re readily and becomes more quickly stable than normal conditioning. ...y the underlying emotional state is of enormous intensity to furnish the ...er so much more rapid conditioning than occurs with the normal condi-...f either food reflexes or defense reflexes to pain. Furthermore we see from ... with which the light becomes a conditional stimulus for the emotional ...responses that pathological secondary chain crs can be elaborated more than can normal chain crs. From this and numerous other experiments it ...hat any stimulus occurring in the same immediate milieu with the patho-...ate can later elicit this state. Thus a sharp whistle by one of the experi-... (H.L.) after being repeated several times also elicited exactly the same ...ped anxiety-like pattern of behavior.

...reat potency of the pathologic state as a basis for forming crs has been ...h Nick where only a few repetitions of the L (with one of the original ...h had become excitants of the conflict) was enough to form the L into a ...ic cs. On the other hand, many more repetitions are necessary to form ...y stable food or defense crs.[9]

...e the ease with which psychopathological crs are formed, the prolonged ...ce without external reinforcement and their stability and intensity are ...arked pathological characteristics. The entire history of Nick bears out ...atements; nevertheless I shall cite here two examples in the autonomic ... As regards the heart rate, it was repeatedly shown that the heart rate was ... normal in the presence of real danger such as an attacking cat or bulldog ... was in the situation of conflict. The second instance is evident in the com-... of the sexual reflexes as a component of the total response in the situation ...flict with the sexual crs formed in the ordinary laboratory method. The ...l cr formed in the normal routine manner was very weak and often absent, ... the sexual erection occurring as a component of the response in the situation ...nflict was pronounced and persisted for years without reinforcement. See for ...ple the predominance of this psychopathological form of sexual cr over the ...mal sexual cr in the note under date of June 8, 1939, in Chapter V.

[9] Trigant Burrow's (10) work suggests that there is an element of psychopathology in ordinary human ..., and that perhaps the same principles underlie psychology as psychopathology. The differences ...ent in our work may be largely in the nature of increased intensity of the underlying emotion ...formation of psychopathological reactions. This is a field for further exploration.

It is certain from all the foregoing experiments that we must consider the personal relationships and the interlocking of functions as well as the more specific mechanisms that recur in a stereotyped fashion. And in spite of the many variations we see much in Nick that is basic for the human being.

Though it is as true now in psychopathology as it was in the world of Epictetus 2,000 years ago that we cannot "pretend to alter the nature of things, it is neither wise nor desirable to make the attempt, but accepting things as they are, let us strive to accord our minds with them"—yet, just as we have manipulated to our use discoveries in the other realms of science, precise knowledge of the laws governing human behavior may help us to re-arrange our world to avoid the disasters that result from the combination of a certain individual or groups of individuals with a certain environment.
